LETTER

June 19, 2003

Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Sir:

Under the provisions of 35 U.S.C. § 119 and 37 C.F.R. § 1.55(a), the applicant(s) hereby claim(s) the right of priority based on the following application(s):

<u>Country</u>	<u>Application No.</u>	<u>Filed</u>
DENMARK	PA 2000 00265	February 21, 2000

A certified copy of the above-noted application(s) is(are) attached hereto.

If necessary, the Commissioner is hereby authorized in this, concurrent, and future replies, to charge payment or credit any overpayment to Deposit Account No. 02-2448 for any additional fee required under 37 C.F.R. §§ 1.16 or 1.17; particularly, extension of time fees.

Respectfully submitted,

BIRCH, STEWART, KOLASCH & BIRCH, LLP

By 
Leonard R. Svensson, #30,330

I hereby certify that this correspondence is being deposited with the United States Postal Service as first class mail, postage prepaid, in an envelope to: Commissioner for Patents, P.O. Box 1450, Alexandria, VA 22313-1450, on: June 19, 2003
(Date of Deposit)

BIRCH, STEWART, KOLASCH & BIRCH, LLP

FIELD OF THE INVENTION

Modtaget

The present invention relates to improvements in therapy and prevention of Alzheimer's disease (AD) and other diseases characterized by deposition of amyloid, e.g. characterized by amyloid deposits in the central nervous system (CNS). More specifically, the present invention provides a method for down-regulating (undesired) deposits of amyloid by enabling the production of antibodies against the relevant protein or components thereof in subjects suffering from or in danger of suffering from diseases having a pathology involving amyloid deposition. The invention also provides for methods of producing polypeptides useful in this method as well as for the modified polypeptides as such. Also encompassed by the present invention are nucleic acid fragments encoding the modified polypeptides as well as vectors incorporating these nucleic acid fragments and host cells and cell lines transformed therewith. The invention also provides for a method for the identification of analogues of the deposit polypeptides which are useful in the method of the invention as well as for compositions comprising modified polypeptides or comprising nucleic acids encoding modified polypeptides.

BACKGROUND OF THE INVENTION

Amyloidosis is the extracellular deposition of insoluble protein fibrils leading to tissue damage and disease (Pepys, 1996; Tan et al., 1995; Kelly, 1996). The fibrils form when normally soluble proteins and peptides self-associate in an abnormal manner (Kelly, 1997).

Amyloid is associated with serious diseases including systemic amyloidosis, AD, maturity onset diabetes, Parkinson's disease,

Huntington's disease, fronto-temporal dementia and the prion-related transmissible spongiform encephalopathies (kuru and Creutzfeldt-Jacob disease in humans and scrapie and BSE in sheep and cattle, respectively) and the amyloid plaque formation in for instance Alzheimer's seems to be closely associated with the progression of human disease. In animal models over-expression, or the expression of modified forms, of proteins found in deposits, like the β -amyloid protein, has been shown to induce various symptoms of disease, e.g. Alzheimer's-like symptoms.

There is no specific treatment for amyloid deposition and these diseases are usually fatal.

The subunits of amyloid fibrils may be wild-type, variant or truncated proteins, and similar fibrils can be formed in vitro from oligopeptides and denatured proteins (Bradbury et al., 1960; Filshie et al., 1964; Burke & Rougvie, 1972). The nature of the polypeptide component of the fibrils defines the character of the amyloidosis. Despite large differences in the size, native structure and function of amyloid proteins, all amyloid fibrils are of indeterminate length, unbranched, 70 to 120 Å in diameter, and display characteristic staining with Congo Red (Pepys, 1996). They are characteristic of a cross- β structure (Pauling & Corey, 1951) in which the polypeptide chain is organized in β -sheets. Although the amyloid proteins have very different precursor structures, they can all undergo a structural conversion, perhaps along a similar pathway, to a misfolded form that is the building block of the β -sheet helix protofilament.

This distinctive fibre pattern led to the amyloidoses being called the β -fibrilloses (Glenner, 1980a,b), and the fibril protein of AD was named the β -protein before its secondary structure was known (Glenner & Wong, 1984). The characteristic cross- β diffraction pattern, together with the fibril appearance and tinctorial properties are now the accepted diagnostic hallmarks of amyloid, and suggest that the fibrils, although formed from quite different

protein precursors, share a degree of structural similarity and comprise a structural superfamily, irrespective of the nature of their precursor proteins (Sunde M, Serpell LC, Bartlam M, Fraser PE, Pepys MB, Blake CCFJ Mol Biol 1997 Oct 31;273(3):729-739).

- 5 One of the most widespread and well-known diseases where amyloid deposits in the central nervous system are suggested to have a central role in the progression of the disease, is AD.

AD

Alzheimer's disease (AD) is an irreversible, progressive brain
 10 disorder that occurs gradually and results in memory loss, behavioural and personality changes, and a decline in mental abilities. These losses are related to the death of brain cells and the breakdown of the connections between them. The course of this disease varies from person to person, as does the rate of
 15 decline. On average, AD patients live for 8 to 10 years after they are diagnosed, though the disease can last for up to 20 years.

AD advances by stages, from early, mild forgetfulness to a severe loss of mental function. This loss is known as dementia.
 20 In most people with AD, symptoms first appear after the age of 60, but earlier onsets are not infrequent. The earliest symptoms often include loss of recent memory, faulty judgment, and changes in personality. Often, people in the initial stages of AD think less clearly and forget the names of familiar people
 25 and common objects. Later in the disease, they may forget how to do even simple tasks. Eventually, people with AD lose all reasoning ability and become dependent on other people for their everyday care. Ultimately, the disease becomes so debilitating that patients are bedridden and likely to develop other ill-
 30 nesses and infections. Most commonly, people with AD die from pneumonia.

Although the risk of developing AD increases with age, AD and dementia symptoms are not a part of normal aging. AD and other dementing disorders are caused by diseases that affect the brain. In normal aging, nerve cells in the brain are not lost in large numbers. In contrast, AD disrupts three key processes: Nerve cell communication, metabolism, and repair. This disruption ultimately causes many nerve cells to stop functioning, lose connections with other nerve cells, and die.

At first, AD destroys neurons in parts of the brain that control memory, especially in the hippocampus and related structures. As nerve cells in the hippocampus stop functioning properly, short-term memory fails, and often, a person's ability to do easy and familiar tasks begins to decline. AD also attacks the cerebral cortex, particularly the areas responsible for language and reasoning. Eventually, many other areas of the brain are involved, all these brain regions atrophy (shrink), and the AD patient becomes bedridden, incontinent, totally helpless, and unresponsive to the outside world (source: National Institute on Aging Progress Report on Alzheimer's Disease, 1999).

20 The Impact of AD

AD is the most common cause of dementia among people age 65 and older. It presents a major health problem because of its enormous impact on individuals, families, the health care system, and society as a whole. Scientists estimate that up to 4 million people currently suffer from the disease, and the prevalence doubles every 5 years beyond age 65. It is also estimated that approximately 360,000 new cases (incidence) will occur each year, though this number will increase as the population ages (Brookmeyer et al., 1998).

AD puts a heavy economic burden on society. A recent study in the United States estimated that the annual cost of caring for one AD patient is \$18,408 for a patient with mild AD, \$30,096

for a patient with moderate AD, and \$36,132 for a patient with severe AD. The annual national cost of caring for AD patients in the US is estimated to be slightly over \$50 billion (Leon et al., 1998).

5 Approximately 4 million Americans are 85 or older, and in most industrialized countries, this age group is one of the fastest growing segments of the population. It is estimated that this group will number nearly 8.5 million by the year 2030 in the US; some experts who study population trends suggest that the number
10 could be even greater. As more and more people live longer, the number of people affected by diseases of aging, including AD, will continue to grow. For example, some studies show that nearly half of all people age 85 and older have some form of dementia. (National Institute on Aging Progress Report on
15 Alzheimer's Disease, 1999)

The Main Characteristics of AD

Two abnormal structures in the brain are the hallmarks of AD: amyloid plaques and neurofibrillary tangles (NFT). Plaques are dense, largely insoluble deposits of protein and cellular
20 material outside and around the brain's neurons. Tangles are insoluble twisted fibres that build up inside neurons.

Two types of AD exist: familial AD (FAD), which follows a certain pattern of inheritance, and sporadic AD, where no obvious pattern of inheritance is seen. Because of differences
25 in the age at onset, AD is further described as early-onset (occurring in people younger than 65) or late-onset (occurring in those 65 and older). Early-onset AD is rare (about 10 percent of cases) and generally affects people aged 30 to 60. Some forms of early-onset AD are inherited and run in families. Early-onset
30 AD also often progresses faster than the more common, late-onset form.

All FADs known so far have an early onset, and as many as 50 percent of FAD cases are now known to be caused by defects in three genes located on three different chromosomes. These are mutations in the APP gene on chromosome 21; mutations in a gene 5 on chromosome 14, called presenilin 1; and mutations in a gene on chromosome 1, called presenilin 2. There is as yet no evidence, however, that any of these mutations play a major role in the more common, sporadic or non-familial form of late-onset AD. (National Institute on Aging Progress Report on Alzheimer's 10 Disease, 1999)

Amyloid Plaques

In AD, amyloid plaques develop first in areas of the brain used for memory and other cognitive functions. They consist of largely insoluble deposits of beta amyloid (hereinafter designated A β) - a protein fragment of a larger protein called 15 amyloid precursor protein (APP, the amino acid sequence of which is set forth in SEQ ID NO: 2) - intermingled with portions of neurons and with non-nerve cells such as microglia and astrocytes. It is not known whether amyloid plaques themselves 20 constitute the main cause of AD or whether they are a by-product of the AD process. Certainly, changes in the APP protein can cause AD, as shown in the inherited form of AD caused by mutations in the APP gene, and A β plaque formation seems to be closely associated with the progression of the human disease 25 (Lippa C. F. et al. 1998).

APP

APP is one of many proteins that are associated with cell membranes. After it is made, APP becomes embedded in the nerve cell's membrane, partly inside and partly outside the cell. 30 Recent studies using transgenic mice demonstrate that APP appears to play an important role in the growth and survival of neurons. For example, certain forms and amounts of APP may

protect neurons against both short- and long-term damage and may render damaged neurons better able to repair themselves and help parts of neurons grow after brain injury.

While APP is embedded in the cell membrane, proteases act on particular sites in APP, cleaving it into protein fragments. One protease helps cleave APP to form A β , and another protease cleaves APP in the middle of the amyloid fragment so that A β cannot be formed. The A β formed is of two different lengths, a shorter 40 (or 41) amino acids A β that is relatively soluble and aggregates slowly, and a slightly longer, 42 amino acids "sticky" A β that rapidly forms insoluble clumps. While A β is being formed, it is not yet known exactly how it moves through or around nerve cells. In the final stages of this process, the "sticky" A β aggregates into long filaments outside the cell and, along with fragments of dead and dying neurons and the microglia and astrocytes, forms the plaques that are characteristic of AD in brain tissue.

Some evidence exists that the mutations in APP render more likely that A β will be snipped out of the APP precursor, thus causing either more total A β or relatively more of the "sticky" form to be made. It also appears that mutations in the presenilin genes may contribute to the degeneration of neurons in at least two ways: By modifying A β production or by triggering the death of cells more directly. Other researchers suggest that mutated presenilins 1 and 2 may be involved in accelerating the pace of apoptosis.

It is to expected that as the disease progresses, more and more plaques will be formed, filling more and more of the brain. Studies suggest that it may be that the A β is aggregating and disaggregating at the same time, in a sort of dynamic equilibrium. This raises the hope that it may be possible to break down the plaques even after they have formed. (National Institute on Aging Progress Report on Alzheimer's Disease, 1999).

It is believed that A β is toxic to neurons. In tissue culture studies, researchers observed an increase in death of hippocampal neurons cells engineered to over-express mutated forms of human APP compared to neurons over-expressing the normal human APP (Luo et al., 1999).

Furthermore, overexpression or the expression of modified forms of the A β protein has in animal models been demonstrated to induce Alzheimer-like symptoms, (Hsiao K. et al., 1998)

Given that increased A β generation, its aggregation into plaques, and the resulting neurotoxicity may lead to AD, it is of therapeutic interest to investigate conditions under which A β aggregation into plaques might be slowed down or even blocked.

Presenilins

Mutations in presenilin-1 (S-180) account for almost 50% of all cases of early-onset familial AD (FAD). Around 30 mutations have been identified that give rise to AD. The onset of AD varies with the mutations. Mutations in presenilin-2 account for a much smaller part of the cases of FAD, but is still a significant factor. It is not known whether presenilins are involved in sporadic non-familial AD. The function of the presenilins is not known, but they appear to be involved in the processing of APP to give A β -42 (the longer stickier form of the peptide), since AD patients with presenilin mutations have increased levels of this peptide. It is unclear whether the presenilins also have a role in causing the generation of NFT's. Some suggest that presenilins could also have a more direct role in the degeneration of neurons and neuron death. Presenilin-1 is located at chromosome 14 while presenilin-2 is linked to chromosome 1. If a person harbours a mutated version of just one of these genes he or she is almost certain to develop early onset AD.

There is some uncertainty to whether presenilin-1 is identical to the hypothetical gamma-secretase involved in the processing of APP (Naruse et al., 1998).

Apolipoprotein E

5 Apolipoprotein E is usually associated with cholesterol, but is also found in plaques and tangles of AD brains. While alleles 1-3 do not seem to be involved in AD there is a significant correlation between the presence of the APOE- ϵ 4 allele and development of late AD (Strittmatter et al., 1993). It is,
10 however, a risk factor and not a direct cause as is the case for the presenilin and APP mutations and it is not limited to familial AD.

The ways in which the ApoE ϵ 4 protein increases the likelihood of developing AD are not known with certainty, but one possible
15 theory is that it facilitates A β buildup and this contributes to lowering the age of onset of AD, or the presence or absence of particular APOE alleles may affect the way neurons respond to injury (Buttini et al., 1999).

Also Apo A1 has been shown to be amyloigenic. Intact apo A1 can
20 itself form amyloid-like fibrils *in vitro* that are Congo red positive (Am J Pathol 147 (2): 238-244 (Aug 1995), Wisniewski T, Golabek AA, Kida E, Wisniewski KE, Frangione B).

There seem to be some contradictory results indicating that there is a positive effect of the APOE- ϵ 4 allele in decreasing
25 symptoms of mental loss, compared to other alleles (Stern, Brandt, 1997, Annals of Neurology 41).

Neurofibrillary Tangles

This second hallmark of AD consists of abnormal collections of twisted threads found inside nerve cells. The chief component of

tangles is one form of a protein called tau (τ). In the central nervous system, tau proteins are best known for their ability to bind and help stabilize microtubules, which are one constituent of the cell's internal support structure, or skeleton. However, in AD tau is changed chemically, and this altered tau can no longer stabilize the microtubules, causing them to fall disintegrate. This collapse of the transport system may at first result in malfunctions in communication between nerve cells and may later lead to neuronal death.

10 In AD, chemically altered tau twists into paired helical filaments - two threads of tau that are wound around each other. These filaments are the major substance found in neurofibrillary tangles. In one recent study, researchers found neurofibrillary changes in fewer than 6 percent of the neurons in a particular part of the hippocampus in healthy brains, in more than 43 percent of these neurons in people who died with mild AD, and in 71 percent of these neurons in people who died with severe AD. When the loss of neurons was studied, a similar progression was found. Evidence of this type supports the idea that the formation of tangles and the loss of neurons progress together over the course of AD. (National Institute on Aging Progress Report on Alzheimer's Disease, 1999).

Tauopathies and Tangles

Several neurodegenerative diseases, other than AD, are characterized by the aggregation of tau into insoluble filaments in neurons and glia, leading to dysfunction and death. Very recently, several groups of researchers, who were studying families with a variety of hereditary dementias other than AD, found the first mutations in the tau gene on chromosome 17 (Clark et al., 1998; Hutton et al., 1998; Poorkaj et al., 1998; Spillantini et al., 1998). In these families, mutations in the tau gene cause neuronal cell death and dementia. These disorders which share some characteristics with AD but differ in several impor-

tant respects, are collectively called "fronto temporal dementia and parkinsonism linked to chromosome 17" (FTDP-17). They are diseases such as Parkinson's disease, some forms of amyotrophic lateral sclerosis (ALS), corticobasal degeneration, progressive 5 supranuclear palsy, and Pick's disease, and are all characterized by abnormal aggregation of tau protein.

Other AD-like neurological diseases.

There are important parallels between AD and other neurological diseases, including prion diseases (such as kuru, Creutzfeld- 10 Jacob disease and bovine spongiform encephalitis), Parkinson's disease, Huntington's disease, and fronto-temporal dementia. All involve deposits of abnormal proteins in the brain. AD and prion diseases cause dementia and death, and both are associated with the formation of insoluble amyloid fibrils, but from membrane 15 proteins that are different from each other.

Scientists studying Parkinson's disease, the second most common neurodegenerative disorder after AD, discovered the first gene linked to the disease. This gene codes for a protein called synuclein, which, intriguingly, is also found in the amyloid 20 plaques of AD patients' brains (Lavedan C, 1998, Genome Res. 8(9): 871-80). Investigators have also discovered that genetic defects in Huntington's disease, another progressive neurodegenerative disorder that causes dementia, cause the Huntington protein to form into insoluble fibrils very similar 25 to the A β fibrils of AD and the protein fibrils of prion disease, (Scherzinger E, et al., 1999, PNAS U.S.A. 96(8): 4604-9).

Scientists have also discovered a novel gene, which when mutated, is responsible for familial British dementia (FBD), a rare inherited disease that causes severe movement disorders and 30 progressive dementia similar to that seen in AD. In a biochemical analysis of the amyloid fibrils found in the FBD plaques, a unique peptide named ABri was found (Vidal et al., 1999). A

mutation at a particular point along this gene results in the production of a longer-than-normal Bri protein. The ABri peptide, which is snipped from the mutated end of the Bri protein is deposited as amyloid fibrils. These plaques are thought to lead to the neuronal dysfunction and dementia that characterizes FBD.

Immunization with A β

The immune system will normally take part in the clearing of foreign protein and proteinaceous particles in the organism but the deposits associated with the above-mentioned diseases consist mainly of self-proteins, thereby rendering the role of the immune system in the control of these diseases less obvious. Further, the deposits are located in a compartment (the CNS) normally separated from the immune system, both facts suggesting that any vaccine or immunotherapeutical approach would be unsuccessful.

Nevertheless, scientists have recently attempted immunizing mice with a vaccine composed of heterologous human A β and a substance known to excite the immune system (Schenk et al., 1999 and WO 99/27944). The vaccine was tested in a partial transgenic mouse model of AD with a human mutated gene for APP inserted into the DNA of the mouse. The mice produced the modified APP protein and developed amyloid plaques as they grew older. This mouse model was used to test whether vaccination against the modified transgenic human APP had an effect on plaque build-up. In a first experiment, one group of transgenic mice was given monthly injections of the vaccine starting at 6 weeks of age and ending at 11 months. A second group of transgenic mice received no injections and served as a control group. By 13 months of age, the mice in the control group had plaques covering 2 to 6 percent of their brains. In contrast, the immunized mice had virtually no plaques.

In a second experiment, the researchers began the injections at 11 months, when some plaques had already developed. Over a 7-month period, the control transgenic mice had a 17-fold increase in the amount of plaque in their brains, whereas those 5 who received the vaccine had a 99-percent decrease compared to the 18-month-old control transgenic mice. In some mice, some of the pre-existing plaque deposits appeared to have been removed by the treatment. It was also found that other plaque-associated damage, such as inflammation and abnormal nerve cell processes, 10 lessened as a result of the immunization.

The above is thus a preliminary study in mice and for example, scientists need to find out whether vaccinated mice remain healthy in other respects and whether memory of those vaccinated remains normal. Furthermore, because the mouse model is not a 15 complete representation of AD (the animals do not develop neurofibrillary tangles nor do many of their neurons die), additional studies will be necessary to determine whether humans have a similar or different reaction from mice. Another issue to consider is that the method may perhaps "cure" amyloid deposi- 20 tion but fail to stop development of dementia.

Technical issues present major challenges as well. For example it is unlikely that it is even possible, using this technology, to create a vaccine which enables humans to raise antibodies against their own proteins. So numerous issues of safety and 25 effectiveness will need to be resolved before any tests in humans can be considered.

The work by Schenk et al. thus shows that if it was possible to generate a strong immune response towards self-proteins in proteinaceous deposits in the central nervous system such as the 30 plaques formed in AD, it is possible to both prevent the formation of the deposits and possibly also clear already formed plaques.

OBJECT OF THE INVENTION

The object of the present invention is to provide novel therapies against conditions characterized by deposition of amyloid, such as AD. A further object is to develop an autovaccine
5 against amyloid, in order to obtain a novel treatment for AD and for other pathological disorders involving amyloid deposition.

SUMMARY OF THE INVENTION

Described herein is the use of an autovaccination technology for generating strong immune responses against otherwise non-
10 immunogenic self-proteins included in pathology-related amyloid deposits. Thereby, a strong immune response is generated against either the amyloid, against one or more of the components included in the deposits, or against one or more of the proteins responsible for amyloid formation. Described is also the prepa-
15 ration of such vaccines for the prevention, possible cure or alleviation of the symptoms of such diseases associated with amyloid deposits.

Thus, in its broadest and most general scope, the present invention relates to a method for *in vivo* down-regulation of amyloid
20 in an animal, including a human being, the method comprising effecting presentation to the animal's immune system of an immunologically effective amount of

- at least one amyloidogenic polypeptide or subsequence thereof which has been formulated so that immunization of
25 the animal with the amyloidogenic polypeptide or subsequence thereof induces production of antibodies against the amyloidogenic polypeptide, and/or
- at least one amyloid analogue wherein is introduced a
30 modification in the amyloidogenic polypeptide which has as a result that immunization of the animal with the analogue

induces production of antibodies against the amyloidogenic polypeptide.

Hence, encompassed by the present invention is the use of 1) naturally occurring antigens and fragments thereof formulated so as to trigger an immune response as well as of 2) analogues of such naturally occurring antigens, the analogues being capable of inducing cross-reactive immune responses.

The invention also relates to analogues of the amyloidogenic polypeptides as well as to nucleic acid fragments encoding a subset of these. Also immunogenic compositions comprising the analogues or the nucleic acid fragments are part of the invention.

The invention also relates to a method of identifying immunogenically effective analogues of amyloidogenic polypeptides as well as a method for preparing a composition comprising the analogues.

LEGEND TO THE FIGURE

Fig. 1: Schematic depiction of Autovac variants derived from the amyloid precursor protein with the purpose of generating antibody responses against the A β protein A β -43 (or C-100). The APP is shown schematically at the top of the figure and the remaining schematic constructs show that the model epitopes P2 and P30 are substituted or inserted into various truncations of APP. In the figure, the black pattern indicates the APP signal sequence, medium grey is the extracellular part of APP, dark grey is the transmembrane domain of APP, light grey is the intracellular domain of APP, coarse cross-hatching indicates the P30 epitope, and fine cross-hatching indicates the P2 epitope. The full line box indicates A β -42/43 and the full-line box and the dotted line box together indicate C-100. "Abeta" denotes A β .

DETAILED DISCLOSURE OF THE INVENTION

Definitions

In the following a number of terms used in the present specification and claims will be defined and explained in detail in order to clarify the metes and bounds of the invention.

The terms "amyloid" and "amyloid protein" which are used interchangeably herein denote a class of proteinaceous unbranched fibrils of indeterminate length. Amyloid fibrils display characteristic staining with Congo Red and share a cross- β structure in which the polypeptide chain is organized in β -sheets. Amyloid is generally derived from amyloidogenic proteins which have very different precursor structures but which can all undergo a structural conversion to a misfolded form that is the building block of the β -sheet helix protofilament. Normally, the diameter of amyloid fibrils varies between about 70 to about 120 Å.

The term "amyloidogenic protein" is intended to denote a polypeptide which is involved in the formation of amyloid deposits, either by being part of the deposits as such or by being part of the biosynthetic pathway leading to the formation of the deposits. Hence, examples of amyloidogenic proteins are APP and A β , but also proteins involved in the metabolism of these may be amyloidogenic proteins. A number of amyloidogenic polypeptides are discussed in detail herein.

An "amyloid polypeptide" is herein intended to denote polypeptides comprising the amino acid sequence of the above-discussed amyloidogenic proteins derived from humans or other mammals (or truncates thereof sharing a substantial amount of B-cell epitopes with an intact amyloidogenic protein) - an amyloidogenic polypeptide can therefore e.g. comprise substantial parts of a

precursor for the amyloidogenic polypeptide (in the case of A β , one possible amyloid polypeptide could be APP derived). Also unglycosylated forms of amyloidogenic polypeptides which are prepared in prokaryotic system are included within the boundaries of the term as are forms having varying glycosylation patterns due to the use of e.g. yeasts or other non-mammalian eukaryotic expression systems. It should, however, be noted that when using the term "an amyloidogenic polypeptide" it is intended that the polypeptide in question is normally non-immunogenic when presented to the animal to be treated. In other words, the amyloidogenic polypeptide is a self-protein or is an analogue of such a self-protein which will not normally give rise to an immune response against the amyloidogenic of the animal in question.

15 An "analogue of an amyloidogenic polypeptide" is an amyloidogenic polypeptide which has been subjected to changes in its primary structure. Such a change can e.g. be in the form of fusion of an amyloid polypeptide to a suitable fusion partner (i.e. a change in primary structure exclusively involving C- and/or N-terminal additions of amino acid residues) and/or it can be in the form of insertions and/or deletions and/or substitutions in the amyloidogenic polypeptide's amino acid sequence. Also encompassed by the term are derivatized amyloidogenic molecules, cf. the discussion below of modifications of amyloidogenic polypeptides. In case the amyloidogenic polypeptide is an amyloid or a precursor therefore, the analogue may be constructed so as to be less able or even unable to elicit antibodies against the normal precursor protein(s) of the amyloid, thereby avoiding undesired interference with the (physiologically normal) non-aggregated form of the polypeptide being a precursor of the amyloid protein.

It should be noted that the use as a vaccine in a human of a xeno-analogue (e.g. a canine or porcine analogue) of a human amyloidogenic polypeptide can be imagined to produce the desired

immunity against the amyloidogenic polypeptide. Such use of an xeno-analogue for immunization is also considered part of the invention.

The term "polypeptide" is in the present context intended to mean both short peptides of from 2 to 10 amino acid residues, oligopeptides of from 11 to 100 amino acid residues, and polypeptides of more than 100 amino acid residues. Furthermore, the term is also intended to include proteins, i.e. functional biomolecules comprising at least one polypeptide; when comprising at least two polypeptides, these may form complexes, be covalently linked, or may be non-covalently linked. The polypeptide(s) in a protein can be glycosylated and/or lipidated and/or comprise prosthetic groups.

The terms "T-lymphocyte" and "T-cell" will be used interchangeably for lymphocytes of thymic origin which are responsible for various cell mediated immune responses as well as for helper activity in the humoral immune response. Likewise, the terms "B-lymphocyte" and "B-cell" will be used interchangeably for antibody-producing lymphocytes.

The term "subsequence" means any consecutive stretch of at least 3 amino acids or, when relevant, of at least 3 nucleotides, derived directly from a naturally occurring amyloid amino acid sequence or nucleic acid sequence, respectively.

The term "animal" is in the present context in general intended to denote an animal species (preferably mammalian), such as *Homo sapiens*, *Canis domesticus*, etc. and not just one single animal. However, the term also denotes a population of such an animal species, since it is important that the individuals immunized according to the method of the invention all harbour substantially the same amyloidogenic polypeptide allowing for immunization of the animals with the same immunogen(s). If, for instance, genetic variants of the amyloidogenic polypeptide exists

in different human population it may be necessary to use different immunogens in these different populations in order to be able to break the autotolerance towards the amyloidogenic polypeptide in each population in an optimum fashion. It will be clear to the skilled person that an animal in the present context is a living being which has an immune system. It is preferred that the animal is a vertebrate, such as a mammal.

By the term "in vivo down-regulation of amyloid" is herein meant reduction in the living organism of the total amount of deposited amyloid of the relevant type. The down-regulation can be obtained by means of several mechanisms: Of these, simple interference with amyloid by antibody binding so as to prevent misaggregation is the most simple. However, it is also within the scope of the present invention that the antibody binding results in removal of amyloid by scavenger cells (such as macrophages and other phagocytic cells) and that the antibodies interferes with other amyloidogenic polypeptides which lead to amyloid formation.

The expression "effecting presentation ... to the immune system" is intended to denote that the animal's immune system is subjected to an immunogenic challenge in a controlled manner. As will appear from the disclosure below, such challenge of the immune system can be effected in a number of ways of which the most important are vaccination with polypeptide containing "pharmaccines" (i.e. a vaccine which is administered to treat or ameliorate ongoing disease) or nucleic acid "pharmaccine" vaccination. The important result to achieve is that immune competent cells in the animal are confronted with the antigen in an immunologically effective manner, whereas the precise mode of achieving this result is of less importance to the inventive idea underlying the present invention.

The term "immunogenically effective amount" has its usual meaning in the art, i.e. an amount of an immunogen which is capable

of inducing an immune response which significantly engages pathogenic agents which share immunological features with the immunogen.

When using the expression that the amyloidogenic polypeptide has been "modified" is herein meant a chemical modification of the polypeptide which constitutes the backbone of the amyloidogenic polypeptide. Such a modification can e.g. be derivatization (e.g. alkylation) of certain amino acid residues in the sequence of the amyloidogenic polypeptide, but as will be appreciated from the disclosure below, the preferred modifications comprise changes of the primary structure of the amino acid sequence.

When discussing "autotolerance towards an amyloidogenic polypeptide" it is understood that since the amyloidogenic polypeptide is a self-protein in the population to be vaccinated, normal individuals in the population do not mount an immune response against the amyloidogenic polypeptide; it cannot be excluded, though, that occasional individuals in an animal population might be able to produce antibodies against native amyloidogenic polypeptide, e.g. as part of an autoimmune disorder. At any rate, an animal will normally only be autotolerant towards its own amyloidogenic polypeptide, but it cannot be excluded that analogues derived from other animal species or from a population having a different phenotype would also be tolerated by said animal.

A "foreign T-cell epitope" (or: "foreign T-lymphocyte epitope") is a peptide which is able to bind to an MHC molecule and which stimulates T-cells in an animal species. Preferred foreign T-cell epitopes in the invention are "promiscuous" epitopes, i.e. epitopes which bind to a substantial fraction of a particular class of MHC molecules in an animal species or population. Only a very limited number of such promiscuous T-cell epitopes are known, and they will be discussed in detail below. It should be noted that in order for the immunogens which are used according

to the present invention to be effective in as large a fraction of an animal population as possible, it may be necessary to 1) insert several foreign T-cell epitopes in the same analogue or 2) prepare several analogues wherein each analogue has a different promiscuous epitope inserted. It should be noted also that the concept of foreign T-cell epitopes also encompasses use of cryptic T-cell epitopes, i.e. epitopes which are derived from a self-protein and which only exerts immunogenic behaviour when existing in isolated form without being part of the self-protein in question.

A "foreign T helper lymphocyte epitope" (a foreign T_H epitope) is a foreign T cell epitope which binds an MHC Class II molecule and can be presented on the surface of an antigen presenting cell (APC) bound to the MHC Class II molecule.

A "functional part" of a (bio)molecule is in the present context intended to mean the part of the molecule which is responsible for at least one of the biochemical or physiological effects exerted by the molecule. It is well-known in the art that many enzymes and other effector molecules have an active site which is responsible for the effects exerted by the molecule in question. Other parts of the molecule may serve a stabilizing or solubility enhancing purpose and can therefore be left out if these purposes are not of relevance in the context of a certain embodiment of the present invention. For instance it is possible to use certain cytokines as a modifying moiety in an amyloidogenic polypeptide (cf. the detailed discussion below), and in such a case, the issue of stability may be irrelevant since the coupling to the amyloidogenic polypeptide may provide the stability necessary.

The term "adjuvant" has its usual meaning in the art of vaccine technology, i.e. a substance or a composition of matter which is 1) not in itself capable of mounting a specific immune response against the immunogen of the vaccine, but which is 2) neverthe-

less capable of enhancing the immune response against the immunogen. Or, in other words, vaccination with the adjuvant alone does not provide an immune response against the immunogen, vaccination with the immunogen may or may not give rise to an
5 immune response against the immunogen, but the combined vaccination with immunogen and adjuvant induces an immune response against the immunogen which is stronger than that induced by the immunogen alone.

"Targeting" of a molecule is in the present context intended to
10 denote the situation where a molecule upon introduction in the animal will appear preferentially in certain tissue(s) or will be preferentially associated with certain cells or cell types. The effect can be accomplished in a number of ways including formulation of the molecule in composition facilitating target-
15 ing or by introduction in the molecule of groups which facilitates targeting. These issues will be discussed in detail below.

"Stimulation of the immune system" means that a substance or composition of matter exhibits a general, non-specific immunostimulatory effect. A number of adjuvants and putative
20 adjuvants (such as certain cytokines) share the ability to stimulate the immune system. The result of using an immunostimulating agent is an increased "alertness" of the immune system meaning that simultaneous or subsequent immunization with an immunogen induces a significantly more effective
25 immune response compared to isolated use of the immunogen

Preferred embodiments of amyloid down-regulation

It is preferred that the amyloidogenic polypeptide used as an immunogen in the method of the invention is a modified molecule wherein at least one change is present in the amino acid sequen-
30 ce of the amyloidogenic polypeptide, since the chances of obtaining the all-important breaking of autotolerance towards the amyloidogenic polypeptide is greatly facilitated that way.

It should be noted that this does not exclude the possibility of using such a modified amyloidogenic polypeptide in formulations which further facilitate the breaking of autotolerance against the amyloidogenic polypeptide, e.g. formulations containing
5 adjuvants.

It has been shown (in Dalum I *et al.*, 1996, J. Immunol. 157: 4796-4804) that potentially self-reactive B-lymphocytes recognizing self-proteins are physiologically present in normal individuals. However, in order for these B-lymphocytes to be
10 induced to actually produce antibodies reactive with the relevant self-proteins, assistance is needed from cytokine producing T-helper lymphocytes (T_H -cells or T_H -lymphocytes). Normally this help is not provided because T-lymphocytes in general do not recognize T-cell epitopes derived from self-proteins when pre-
15 sented by antigen presenting cells (APCs). However, by providing an element of "foreignness" in a self-protein (*i.e.* by introducing an immunologically significant modification), T-cells recognizing the foreign element are activated upon recognizing the foreign epitope on an APC (such as, initially, a mononuclear
20 cell). Polyclonal B-lymphocytes (which are also APCs) capable of recognising self-epitopes on the modified self-protein also internalise the antigen and subsequently presents the foreign T-cell epitope(s) thereof, and the activated T-lymphocytes subsequently provide cytokine help to these self-reactive polyclonal
25 B-lymphocytes. Since the antibodies produced by these polyclonal B-lymphocytes are reactive with different epitopes on the modified polypeptide, including those which are also present in the native polypeptide, an antibody cross-reactive with the non-modified self-protein is induced. In conclusion, the T-lympho-
30 cytes can be led to act as if the population of polyclonal B-lymphocytes have recognised an entirely foreign antigen, whereas in fact only the inserted epitope(s) is/are foreign to the host. In this way, antibodies capable of cross-reacting with non-modified self-antigens are induced.

Several ways of modifying a peptide self-antigen in order to obtain breaking of autotolerance are known in the art. Hence, according to the invention, the modification can include that

- at least one foreign T-cell epitope is introduced, and/or
- 5 - at least one first moiety is introduced which effects targeting of the modified molecule to an antigen presenting cell (APC), and/or
- at least one second moiety is introduced which stimulates the immune system, and/or
- 10 - at least one third moiety is introduced which optimizes presentation of the modified amyloidogenic polypeptide to the immune system.

However, all these modifications should be carried out while maintaining a substantial fraction of the original B-lymphocyte
15 epitopes in the amyloidogenic polypeptide, since the B-lymphocyte recognition of the native molecule is thereby enhanced.

In one preferred embodiment, side groups (in the form of foreign T-cell epitopes or the above-mentioned first, second and third moieties) are covalently or non-covalently introduced. This is
20 to mean that stretches of amino acid residues derived from the amyloidogenic polypeptide are derivatized without altering the primary amino acid sequence, or at least without introducing changes in the peptide bonds between the individual amino acids in the chain.

25 An alternative, and preferred, embodiment utilises amino acid substitution and/or deletion and/or insertion and/or addition (which may be effected by recombinant means or by means of peptide synthesis; modifications which involves longer stretches of amino acids can give rise to fusion polypeptides). One espe-
30 cially preferred version of this embodiment is the technique described in WO 95/05849, which discloses a method for down-regulating self-proteins by immunising with analogues of the

self-proteins wherein a number of amino acid sequence(s) has been substituted with a corresponding number of amino acid sequence(s) which each comprise a foreign immunodominant T-cell epitope, while at the same time maintaining the overall tertiary structure of the self-protein in the analogue. For the purposes of the present invention, it is however sufficient if the modification (be it an insertion, addition, deletion or substitution) gives rise to a foreign T-cell epitope and at the same time preserves a substantial number of the B-cell epitopes in the amyloidogenic polypeptide. However, in order to obtain maximum efficacy of the immune response induced, it is preferred that the overall tertiary structure of the amyloidogenic polypeptide is maintained in the modified molecule.

The following formula describes the molecular constructs generally covered by the invention:

$$(\text{MOD}_1)_{s_1}(\text{amyloid}_{e1})_{n_1}(\text{MOD}_2)_{s_2}(\text{amyloid}_{e2})_{n_2}\dots(\text{MOD}_x)_{s_x}(\text{amyloid}_{ex})_{n_x} \quad (\text{I})$$

-where amyloid_{e1}-amyloid_{ex} are x B-cell epitope containing subsequences of an amyloidogenic polypeptide which independently are identical or non-identical and which may contain or not contain foreign side groups, x is an integer ≥ 3 , n₁-n_x are x integers ≥ 0 (at least one is ≥ 1), MOD₁-MOD_x are x modifications introduced between the preserved B-cell epitopes, and s₁-s_x are x integers ≥ 0 (at least one is ≥ 1 if no side groups are introduced in the amyloid_{ex} sequences). Thus, given the general functional restraints on the immunogenicity of the constructs, the invention allows for all kinds of permutations of the original sequence of the amyloidogenic polypeptide, and all kinds of modifications therein. Thus, included in the invention are modified amyloidogenic polypeptides obtained by omission of parts of the sequence of the amyloidogenic polypeptide which e.g. exhibit adverse effects *in vivo* or omission of parts which are normally intracellular and thus could give rise to undesired immunological reactions.

One preferred version of the constructs outlined above are, when applicable, those where the B-cell epitope containing subsequence of an amyloid protein is not extracellularly exposed in the precursor polypeptide from which the amyloid is derived. By making such a choice of the amyloid epitopes, it is ensured that antibodies are not generated which would be reactive with the cells producing the amyloid precursor and thereby the immune response which is generated becomes limited to an immune response against the undesired amyloid deposits. A similar choice can, when applicable, be made for other amyloidogenic polypeptides than amyloid. In these cases it will e.g. be feasible to induce immunity against epitopes of the amyloidogenic polypeptide which are only exposed to the extracellular phase when being free from any coupling to the cells from which they are produced.

Maintenance of a substantial fraction of B-cell epitopes or even the overall tertiary structure of a protein which is subjected to modification as described herein can be achieved in several ways. One is simply to prepare a polyclonal antiserum directed against the amyloidogenic polypeptide (e.g. an antiserum prepared in a rabbit) and thereafter use this antiserum as a test reagent (e.g. in a competitive ELISA) against the modified proteins which are produced. Modified versions (analogues) which react to the same extent with the antiserum as does the amyloidogenic polypeptide must be regarded as having the same overall tertiary structure as the amyloidogenic polypeptide whereas analogues exhibiting a limited (but still significant and specific) reactivity with such an antiserum are regarded as having maintained a substantial fraction of the original B-cell epitopes.

Alternatively, a selection of monoclonal antibodies reactive with distinct epitopes on the amyloidogenic polypeptide can be prepared and used as a test panel. This approach has the advantage of allowing 1) an epitope mapping of the amyloidogenic

polypeptide and 2) a mapping of the epitopes which are maintained in the analogues prepared.

Of course, a third approach would be to resolve the 3-dimensional structure of the amyloidogenic polypeptide or of a
5 biologically active truncate thereof (cf. above) and compare this to the resolved three-dimensional structure of the analogues prepared. Three-dimensional structure can be resolved by the aid of X-ray diffraction studies and NMR-spectroscopy. Further information relating to the tertiary structure can to
10 some extent be obtained from circular dichroism studies which have the advantage of merely requiring the polypeptide in pure form (whereas X-ray diffraction requires the provision of crystallized polypeptide and NMR requires the provision of isotopic variants of the polypeptide) in order to provide useful
15 information about the tertiary structure of a given molecule. However, ultimately X-ray diffraction and/or NMR are necessary to obtain conclusive data since circular dichroism can only provide indirect evidence of correct 3-dimensional structure via information of secondary structure elements.

20 One preferred embodiment of the invention utilises multiple presentations of B-lymphocyte epitopes of the amyloidogenic polypeptide (i.e. formula I wherein at least one B-cell epitope is present in two positions). This effect can be achieved in various ways, e.g. by simply preparing fusion polypeptides
25 comprising the structure (amyloidogenic polypeptide)_m, where m is an integer ≥ 2 and then introduce the modifications discussed herein in at least one of the amyloid sequences. It is preferred that the modifications introduced includes at least one duplication of a B-lymphocyte epitope and/or the introduction of a
30 hapten.

As mentioned above, the introduction of a foreign T-cell epitope can be accomplished by introduction of at least one amino acid insertion, addition, deletion, or substitution. Of course, the

normal situation will be the introduction of more than one change in the amino acid sequence (e.g. insertion of or substitution by a complete T-cell epitope) but the important goal to reach is that the analogue, when processed by an antigen presenting cell (APC), will give rise to such a foreign immunodominant T-cell epitope being presented in context of an MCH Class II molecule on the surface of the APC. Thus, if the amino acid sequence of the amyloidogenic polypeptide in appropriate positions comprises a number of amino acid residues which can also be found in a foreign T_H epitope then the introduction of a foreign T_H epitope can be accomplished by providing the remaining amino acids of the foreign epitope by means of amino acid insertion, addition, deletion and substitution. In other words, it is not necessary to introduce a complete T_H epitope by insertion or substitution in order to fulfill the purpose of the present invention.

It is preferred that the number of amino acid insertions, deletions, substitutions or additions is at least 2, such as 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, and 25 insertions, substitutions, additions or deletions. It is furthermore preferred that the number of amino acid insertions, substitutions, additions or deletions is not in excess of 150, such as at most 100, at most 90, at most 80, and at most 70. It is especially preferred that the number of substitutions, insertions, deletions, or additions does not exceed 60, and in particular the number should not exceed 50 or even 40. Most preferred is a number of not more than 30. With respect to amino acid additions, it should be noted that these, when the resulting construct is in the form of a fusion polypeptide, is often considerably higher than 150.

Preferred embodiments of the invention includes modification by introducing at least one foreign immunodominant T-cell epitope. It will be understood that the question of immune dominance of a T-cell epitope depends on the animal species in question. As

used herein, the term "immunodominance" simply refers to epitopes which in the vaccinated individual/population gives rise to a significant immune response, but it is a well-known fact that a T-cell epitope which is immunodominant in one individual/population is not necessarily immunodominant in another individual of the same species, even though it may be capable of binding MHC-II molecules in the latter individual. Hence, for the purposes of the present invention, an immune dominant T-cell epitope is a T-cell epitope which will be effective in providing T-cell help when present in an antigen. Typically, immune dominant T-cell epitopes has as an inherent feature that they will substantially always be presented bound to an MHC Class II molecule, irrespective of the polypeptide wherein they appear.

Another important point is the issue of MHC restriction of T-cell epitopes. In general, naturally occurring T-cell epitopes are MHC restricted, i.e. a certain peptides constituting a T-cell epitope will only bind effectively to a subset of MHC Class II molecules. This in turn has the effect that in most cases the use of one specific T-cell epitope will result in a vaccine component which is only effective in a fraction of the population, and depending on the size of that fraction, it can be necessary to include more T-cell epitopes in the same molecule, or alternatively prepare a multi-component vaccine wherein the components are variants of the amyloidogenic polypeptide which are distinguished from each other by the nature of the T-cell epitope introduced.

If the MHC restriction of the T-cells used is completely unknown (for instance in a situation where the vaccinated animal has a poorly defined MHC composition), the fraction of the population covered by a specific vaccine composition can be determined by means of the following formula

$$f_{\text{population}} = 1 - \prod_{i=1}^n (1 - p_i) \quad (\text{II})$$

-where p_i is the frequency in the population of responders to the i^{th} foreign T-cell epitope present in the vaccine composition, and n is the total number of foreign T-cell epitopes in the vaccine composition. Thus, a vaccine composition containing 5 3 foreign T-cell epitopes having response frequencies in the population of 0.8, 0.7, and 0.6, respectively, would give

$$1 - 0.2 \times 0.3 \times 0.4 = 0.976$$

-i.e. 97.6 percent of the population will statistically mount an MHC-II mediated response to the vaccine.

10 The above formula does not apply in situations where a more or less precise MHC restriction pattern of the peptides used is known. If, for instance a certain peptide only binds the human MHC-II molecules encoded by HLA-DR alleles DR1, DR3, DR5, and DR7, then the use of this peptide together with another peptide 15 which binds the remaining MHC-II molecules encoded by HLA-DR alleles will accomplish 100% coverage in the population in question. Likewise, if the second peptide only binds DR3 and DR5, the addition of this peptide will not increase the coverage at all. If one bases the calculation of population response 20 purely on MHC restriction of T-cell epitopes in the vaccine, the fraction of the population covered by a specific vaccine composition can be determined by means of the following formula:

$$f_{\text{population}} = 1 - \prod_{j=1}^3 (1 - \phi_j)^2 \quad (\text{III})$$

-wherein ϕ_j is the sum of frequencies in the population of 25 allelic haplotypes encoding MHC molecules which bind any one of the T-cell epitopes in the vaccine and which belong to the j^{th} of the 3 known HLA loci (DP, DR and DQ); in practice, it is first determined which MHC molecules will recognize each T-cell epitope in the vaccine and thereafter these are listed by type 30 (DP, DR and DQ) - then, the individual frequencies of the

different listed allelic haplotypes are summed for each type, thereby yielding ϕ_1 , ϕ_2 , and ϕ_3 .

It may occur that the value p_i in formula II exceeds the corresponding theoretical value π_i :

$$\pi_i = 1 - \prod_{j=1}^3 (1 - v_j)^2 \quad (\text{IV})$$

-wherein v_j is the sum of frequencies in the population of allelic haplotype encoding MHC molecules which bind the i^{th} T-cell epitope in the vaccine and which belong to the j^{th} of the 3 known HLA loci (DP, DR and DQ). This means that in $1 - \pi_i$ of the population is a frequency of responders of $f_{\text{residual}_i} = (p_i - \pi_i) / (1 - \pi_i)$. Therefore, formula III can be adjusted so as to yield formula V:

$$f_{\text{population}} = 1 - \prod_{j=1}^3 (1 - \phi_j)^2 + \left(1 - \prod_{i=1}^n (1 - f_{\text{residual}_i}) \right) \quad (\text{V})$$

-where the term $1 - f_{\text{residual}_i}$ is set to zero if negative. It should be noted that formula V requires that all epitopes have been haplotype mapped against identical sets of haplotypes.

Therefore, when selecting T-cell epitopes to be introduced in the analogue, it is important to include all knowledge of the epitopes which is available: 1) The frequency of responders in the population to each epitope, 2) MHC restriction data, and 3) frequency in the population of the relevant haplotypes.

There exist a number of naturally occurring "promiscuous" T-cell epitopes which are active in a large proportion of individuals of an animal species or an animal population and these are preferably introduced in the vaccine thereby reducing the need for a very large number of different analogues in the same vaccine.

The promiscuous epitope can according to the invention be a naturally occurring human T-cell epitope such as epitopes from tetanus toxoid (e.g. the P2 and P30 epitopes), diphtheria toxoid, Influenza virus hemagglutinin (HA), and *P. falciparum* CS
5 antigen.

Over the years a number of other promiscuous T-cell epitopes have been identified. Especially peptides capable of binding a large proportion of HLA-DR molecules encoded by the different HLA-DR alleles have been identified and these are all possible
10 T-cell epitopes to be introduced in the analogues used according to the present invention. Cf. also the epitopes discussed in the following references which are hereby all incorporated by reference herein: WO 98/23635 (Frazer IH et al., assigned to The University of Queensland); Southwood S et. al, 1998, J. Immunol.
15 160: 3363-3373; Sinigaglia F et al., 1988, Nature 336: 778-780; Chicz RM et al., 1993, J. Exp. Med 178: 27-47; Hammer J et al., 1993, Cell 74: 197-203; and Falk K et al., 1994, Immunogenetics 39: 230-242. The latter reference also deals with HLA-DQ and -DP ligands. All epitopes listed in these 5 references are relevant
20 as candidate natural epitopes to be used in the present invention, as are epitopes which share common motifs with these.

Alternatively, the epitope can be any artificial T-cell epitope which is capable of binding a large proportion of MHC Class II molecules. In this context the pan DR epitope peptides ("PADRE")
25 described in WO 95/07707 and in the corresponding paper Alexander J et al., 1994, Immunity 1: 751-761 (both disclosures are incorporated by reference herein) are interesting candidates for epitopes to be used according to the present invention. It should be noted that the most effective PADRE peptides disclosed
30 in these papers carry D-amino acids in the C- and N-termini in order to improve stability when administered. However, the present invention primarily aims at incorporating the relevant epitopes as part of the modified amyloidogenic polypeptide which should then subsequently be broken down enzymatically inside the

lysosomal compartment of APCs to allow subsequent presentation in the context of an MHC-II molecule and therefore it is not expedient to incorporate D-amino acids in the epitopes used in the present invention.

- 5 One especially preferred PADRE peptide is the one having the amino acid sequence AKFVAAWTLKAAA or an immunologically effective subsequence thereof. This, and other epitopes having the same lack of MHC restriction are preferred T-cell epitopes which should be present in the analogues used in the inventive method.
- 10 Such super-promiscuous epitopes will allow for the most simple embodiments of the invention wherein only one single modified amyloidogenic polypeptide is presented to the vaccinated animal's immune system.

- As mentioned above, the modification of the amyloidogenic
- 15 polypeptide can also include the introduction of a first moiety which targets the modified amyloidogenic polypeptide to an APC or a B-lymphocyte. For instance, the first moiety can be a specific binding partner for a B-lymphocyte specific surface antigen or for an APC specific surface antigen. Many such
 - 20 specific surface antigens are known in the art. For instance, the moiety can be a carbohydrate for which there is a receptor on the B-lymphocyte or the APC (e.g. mannan or mannose). Alternatively, the second moiety can be a hapten. Also an antibody fragment which specifically recognizes a surface molecule on
 - 25 APCs or lymphocytes can be used as a first moiety (the surface molecule can e.g. be an FC γ receptor of macrophages and monocytes, such as FC γ RI or, alternatively any other specific surface marker such as CD40 or CTLA-4). It should be noted that all these exemplary targeting molecules can be used as part of
 - 30 an adjuvant also, cf. below.

As an alternative or supplement to targeting the modified amyloidogenic polypeptide to a certain cell type in order to achieve an enhanced immune response, it is possible to increase

the level of responsiveness of the immune system by including the above-mentioned second moiety which stimulates the immune system. Typical examples of such second moieties are cytokines, and heat-shock proteins or molecular chaperones, as well as
5 effective parts thereof.

Suitable cytokines to be used according to the invention are those which will normally also function as adjuvants in a vaccine composition, i.e. for instance interferon γ (IFN- γ), interleukin 1 (IL-1), interleukin 2 (IL-2), interleukin 4 (IL-
10 4), interleukin 6 (IL-6), interleukin 12 (IL-12), interleukin 13 (IL-13), interleukin 15 (IL-15), and granulocyte-macrophage colony stimulating factor (GM-CSF); alternatively, the functional part of the cytokine molecule may suffice as the second moiety. With respect to the use of such cytokines as adjuvant
15 substances, cf. the discussion below.

According to the invention, suitable heat-shock proteins or molecular chaperones used as the second moiety can be HSP70, HSP90, HSC70, GRP94 (also known as gp96, cf. Wearsch PA et al. 1998, Biochemistry 37: 5709-19), and CRT (calreticulin).

- 20 Alternatively, the second moiety can be a toxin, such as listeriolysin (LLO), lipid A and heat-labile enterotoxin. Also, a number of mycobacterial derivatives such as MDP (muramyl dipeptide), CFA (complete Freund's adjuvant) and the trehalose diesters TDM and TDE are interesting possibilities.
- 25 Also the possibility of introducing a third moiety which enhances the presentation of the modified amyloidogenic polypeptide to the immune system is an important embodiment of the invention. The art has shown several examples of this principle. For instance, it is known that the palmitoyl lipidation anchor
30 in the *Borrelia burgdorferi* protein OspA can be utilised so as to provide self-adjuvating polypeptides (cf. e.g. WO 96/40718) - it seems that the lipidated proteins form up micelle-like

structures with a core consisting of the lipidation anchor parts of the polypeptides and the remaining parts of the molecule protruding therefrom, resulting in multiple presentations of the antigenic determinants. Hence, the use of this and related approaches using different lipidation anchors (e.g. a myristyl group, a myristyl group, a farnesyl group, a geranyl-geranyl group, a Π -anchor, and an N-acyl diglyceride group) are preferred embodiments of the invention, especially since the provision of such a lipidation anchor in a recombinantly produced protein is fairly straightforward and merely requires use of e.g. a naturally occurring signal sequence as a fusion partner for the modified amyloidogenic polypeptide. Another possibility is use of the C3d fragment of complement factor C3 or C3 itself (cf. Dempsey et al., 1996, Science 271, 348-350 and Lou & Kohler, 1998, Nature Biotechnology 16, 458-462).

An alternative embodiment of the invention which also results in the preferred presentation of multiple (e.g. at least 2) copies of the important epitopic regions of the amyloidogenic polypeptide to the immune system is the covalent coupling of the amyloidogenic polypeptide, subsequence or variants thereof to certain molecules. For instance, polymers can be used, e.g. carbohydrates such as dextran, cf. e.g. Lees A et al., 1994, Vaccine 12: 1160-1166; Lees A et al., 1990, J Immunol. 145: 3594-3600, but also mannose and mannan are useful alternative. Integral membrane proteins from e.g. *E. coli* and other bacteria are also useful conjugation partners. The traditional carrier molecules such as keyhole limpet hemocyanin (KLH), tetanus toxoid, diphtheria toxoid, and bovine serum albumin (BSA) are also preferred and useful conjugation partners.

Considerations underlying chosen areas of introducing modifications in amyloidogenic polypeptides are a) preservation of known and predicted B-cell epitopes, b) preservation of tertiary structure etc. At any rate, as discussed above, it is fairly easy to screen a set of modified amyloidogenic molecules which

have all been subjected to introduction of a T-cell epitope in different locations.

Since the most preferred embodiments of the present invention involve down-regulation of human A β , it is consequently preferred that the amyloid polypeptide discussed above is a human A β polypeptide. In this embodiment, it is especially preferred that the human amyloidogenic polypeptide has been modified by substituting at least one amino acid sequence in SEQ ID NO: 2 with at least one amino acid sequence of equal or different length and containing a foreign T_H epitope. Preferred examples of modified amyloidogenic APP and A β are shown schematically in Fig. 1 using the P2 and P30 epitopes as examples. The rationale behind such constructs is discussed in detail in the example.

More specifically, a T_H containing (or completing) amino acid sequence which is introduced into SEQ ID NO: 2 may be introduced at any amino acid in SEQ ID NO: 2. That is, the introduction is possible after any of amino acids 1-770, but preferably after any of amino acids 671, 672, 673, 674, 675, 676, 677, 678, 679, 680, 681, 682, 683, 684, 685, 686, 687, 688, 689, 690, 691, 692, 693, 694, 695, 696, 697, 698, 699, 700, 701, 702, 703, 704, 705, 706, 707, 708, 709, 710, 711, 712, 713, and 714 in SEQ ID NO: 2. This may be combined with deletion of any or all of amino acids 1-671, or any of all of amino acids 715-770. Furthermore, when utilising the technique of substitution, any one of amino acids 671, 672, 673, 674, 675, 676, 677, 678, 679, 680, 681, 682, 683, 684, 685, 686, 687, 688, 689, 690, 691, 692, 693, 694, 695, 696, 697, 698, 699, 700, 701, 702, 703, 704, 705, 706, 707, 708, 709, 710, 711, 712, 713, and 714 in SEQ ID NO: 2 may be deleted in combination with the introduction.

Formulation of the amyloidogenic polypeptide and modified amyloidogenic polypeptides

When effecting presentation of the amyloidogenic polypeptide or the modified amyloidogenic polypeptide to an animal's immune system by means of administration thereof to the animal, the formulation of the polypeptide follows the principles generally acknowledged in the art.

Preparation of vaccines which contain peptide sequences as active ingredients is generally well understood in the art, as exemplified by U.S. Patents 4,608,251; 4,601,903; 4,599,231; 4,599,230; 4,596,792; and 4,578,770, all incorporated herein by reference. Typically, such vaccines are prepared as injectables either as liquid solutions or suspensions; solid forms suitable for solution in, or suspension in, liquid prior to injection may also be prepared. The preparation may also be emulsified. The active immunogenic ingredient is often mixed with excipients which are pharmaceutically acceptable and compatible with the active ingredient. Suitable excipients are, for example, water, saline, dextrose, glycerol, ethanol, or the like, and combinations thereof. In addition, if desired, the vaccine may contain minor amounts of auxiliary substances such as wetting or emulsifying agents, pH buffering agents, or adjuvants which enhance the effectiveness of the vaccines; cf. the detailed discussion of adjuvants below.

The vaccines are conventionally administered parenterally, by injection, for example, either subcutaneously, intracutaneously, intradermally, subdermally or intramuscularly. Additional formulations which are suitable for other modes of administration include suppositories and, in some cases, oral, buccal, sublingual, intraperitoneal, intravaginal, anal, epidural, spinal, and intracranial formulations. For suppositories, traditional binders and carriers may include, for example, polyalkylene glycols or triglycerides; such suppositories may be

formed from mixtures containing the active ingredient in the range of 0.5% to 10%, preferably 1-2%. Oral formulations include such normally employed excipients as, for example, pharmaceutical grades of mannitol, lactose, starch, magnesium stearate, sodium saccharine, cellulose, magnesium carbonate, and the like. These compositions take the form of solutions, suspensions, tablets, pills, capsules, sustained release formulations or powders and contain 10-95% of active ingredient, preferably 25-70%. For oral formulations, cholera toxin is an interesting formulation partner (and also a possible conjugation partner).

The polypeptides may be formulated into the vaccine as neutral or salt forms. Pharmaceutically acceptable salts include acid addition salts (formed with the free amino groups of the peptide) and which are formed with inorganic acids such as, for example, hydrochloric or phosphoric acids, or such organic acids as acetic, oxalic, tartaric, mandelic, and the like. Salts formed with the free carboxyl groups may also be derived from inorganic bases such as, for example, sodium, potassium, ammonium, calcium, or ferric hydroxides, and such organic bases as isopropylamine, trimethylamine, 2-ethylamino ethanol, histidine, procaine, and the like.

The vaccines are administered in a manner compatible with the dosage formulation, and in such amount as will be therapeutically effective and immunogenic. The quantity to be administered depends on the subject to be treated, including, e.g., the capacity of the individual's immune system to mount an immune response, and the degree of protection desired. Suitable dosage ranges are of the order of several hundred micrograms active ingredient per vaccination with a preferred range from about 0.1 µg to 2,000 µg (even though higher amounts in the 1-10 mg range are contemplated), such as in the range from about 0.5 µg to 1,000 µg, preferably in the range from 1 µg to 500 µg and especially in the range from about 10 µg to 100 µg. Suitable regimens for initial administration and booster shots are also

variable but are typified by an initial administration followed by subsequent inoculations or other administrations.

The manner of application may be varied widely. Any of the conventional methods for administration of a vaccine are applicable. These include oral application on a solid physiologically acceptable base or in a physiologically acceptable dispersion, parenterally, by injection or the like. The dosage of the vaccine will depend on the route of administration and will vary according to the age of the person to be vaccinated and the formulation of the antigen.

Some of the polypeptides of the vaccine are sufficiently immunogenic in a vaccine, but for some of the others the immune response will be enhanced if the vaccine further comprises an adjuvant substance.

Various methods of achieving adjuvant effect for the vaccine are known. General principles and methods are detailed in "The Theory and Practical Application of Adjuvants", 1995, Duncan E.S. Stewart-Tull (ed.), John Wiley & Sons Ltd, ISBN 0-471-95170-6, and also in "Vaccines: New Generation Immunological Adjuvants", 1995, Gregoriadis G et al. (eds.), Plenum Press, New York, ISBN 0-306-45283-9, both of which are hereby incorporated by reference herein.

It is especially preferred to use an adjuvant which can be demonstrated to facilitate breaking of the autotolerance to autoantigens; in fact, this is essential in cases where unmodified amyloidogenic polypeptide is used as the active ingredient in the autovaccine. Non-limiting examples of suitable adjuvants are selected from the group consisting of an immune targeting adjuvant; an immune modulating adjuvant such as a toxin, a cytokine, and a mycobacterial derivative; an oil formulation; a polymer; a micelle forming adjuvant; a saponin; an immunostimulating complex matrix (ISCOM matrix); a particle;

DDA; aluminium adjuvants; DNA adjuvants; γ -inulin; and an encapsulating adjuvant. In general it should be noted that the disclosures above which relate to compounds and agents useful as first, second and third moieties in the analogues also refer
5 *mutatis mutandis* to their use in the adjuvant of a vaccine of the invention.

The application of adjuvants include use of agents such as aluminum hydroxide or phosphate (alum), commonly used as 0.05 to 0.1 percent solution in buffered saline, admixture with syn-
10 thetic polymers of sugars (e.g. Carbopol®) used as 0.25 percent solution, aggregation of the protein in the vaccine by heat treatment with temperatures ranging between 70° to 101°C for 30 second to 2 minute periods respectively and also aggregation by means of cross-linking agents are possible. Aggregation by
15 reactivation with pepsin treated antibodies (Fab fragments) to albumin, mixture with bacterial cells such as *C. parvum* or endotoxins or lipopolysaccharide components of gram-negative bacteria, emulsion in physiologically acceptable oil vehicles such as mannide mono-oleate (Aracel A) or emulsion with 20
20 percent solution of a perfluorocarbon (Fluosol-DA) used as a block substitute may also be employed. Admixture with oils such as squalene and IFA is also preferred.

According to the invention DDA (dimethyldioctadecylammonium bromide) is an interesting candidate for an adjuvant as is DNA
25 and γ -inulin, but also Freund's complete and incomplete adjuvants as well as *quillaja* saponins such as QuilA and QS21 are interesting as is RIBI. Further possibilities are monophosphoryl lipid A (MPL), the above mentioned C3 and C3d, and muramyl dipeptide (MDP).

30 Liposome formulations are also known to confer adjuvant effects, and therefore liposome adjuvants are preferred according to the invention.

Also immunostimulating complex matrix type (ISCOM® matrix) adjuvants are preferred choices according to the invention, especially since it has been shown that this type of adjuvants are capable of up-regulating MHC Class II expression by APCs. An
5 ISCOM® matrix consists of (optionally fractionated) saponins (triterpenoids) from *Quillaja saponaria*, cholesterol, and phospholipid. When admixed with the immunogenic protein, the resulting particulate formulation is what is known as an ISCOM particle where the saponin constitutes 60-70% w/w, the cholesterol and phospholipid 10-15% w/w, and the protein 10-15% w/w.
10 Details relating to composition and use of immunostimulating complexes can e.g. be found in the above-mentioned text-books dealing with adjuvants, but also Morein B et al., 1995, Clin. Immunother. 3: 461-475 as well as Barr IG and Mitchell GF, 1996,
15 Immunol. and Cell Biol. 74: 8-25 (both incorporated by reference herein) provide useful instructions for the preparation of complete immunostimulating complexes.

Another highly interesting (and thus, preferred) possibility of achieving adjuvant effect is to employ the technique described
20 in Gosselin et al., 1992 (which is hereby incorporated by reference herein). In brief, the presentation of a relevant antigen such as an antigen of the present invention can be enhanced by conjugating the antigen to antibodies (or antigen binding antibody fragments) against the Fcγ receptors on
25 monocytes/macrophages. Especially conjugates between antigen and anti-FcγRI have been demonstrated to enhance immunogenicity for the purposes of vaccination.

Other possibilities involve the use of the targeting and immune modulating substances (i.a. cytokines) mentioned above as
30 candidates for the first and second moieties in the modified versions of amyloidogenic polypeptides. In this connection, also synthetic inducers of cytokines like poly I:C are possibilities.

Suitable mycobacterial derivatives are selected from the group consisting of muramyl dipeptide, complete Freund's adjuvant, RIBI, and a diester of trehalose such as TDM and TDE.

5 Suitable immune targeting adjuvants are selected from the group consisting of CD40 ligand and CD40 antibodies or specifically binding fragments thereof (cf. the discussion above), mannose, a Fab fragment, and CTLA-4.

10 Suitable polymer adjuvants are selected from the group consisting of a carbohydrate such as dextran, PEG, starch, mannan, and mannose; a plastic polymer such as; and latex such as latex beads.

Yet another interesting way of modulating an immune response is to include the immunogen (optionally together with adjuvants and pharmaceutically acceptable carriers and vehicles) in a "virtual lymph node" (VLN) (a proprietary medical device developed by ImmunoTherapy, Inc., 360 Lexington Avenue, New York, NY 10017-6501). The VLN (a thin tubular device) mimics the structure and function of a lymph node. Insertion of a VLN under the skin creates a site of sterile inflammation with an upsurge of
20 cytokines and chemokines. T- and B-cells as well as APCs rapidly respond to the danger signals, home to the inflamed site and accumulate inside the porous matrix of the VLN. It has been shown that the necessary antigen dose required to mount an immune response to an antigen is reduced when using the VLN and
25 that immune protection conferred by vaccination using a VLN surpassed conventional immunization using Ribi as an adjuvant. The technology is *i.a.* described briefly in Gelber C et al., 1998, "Elicitation of Robust Cellular and Humoral Immune Responses to Small Amounts of Immunogens Using a Novel Medical
30 Device Designated the Virtual Lymph Node", in: "From the Laboratory to the Clinic, Book of Abstracts, October 12th - 15th 1998, Seascape Resort, Aptos, California".

It is expected that the vaccine should be administered 1-6 times per year, such as 1, 2, 3, 4, 5, or 6 times a year to an individual in need thereof. It has previously been shown that the memory immunity induced by the use of the preferred autovaccines according to the invention is not permanent, and therefore the immune system needs to be periodically challenged with the amyloidogenic polypeptide or modified amyloidogenic polypeptides.

Due to genetic variation, different individuals may react with immune responses of varying strength to the same polypeptide. Therefore, the vaccine according to the invention may comprise several different polypeptides in order to increase the immune response, cf. also the discussion above concerning the choice of foreign T-cell epitope introductions. The vaccine may comprise two or more polypeptides, where all of the polypeptides are as defined above.

The vaccine may consequently comprise 3-20 different modified or unmodified polypeptides, such as 3-10 different polypeptides.

Nucleic acid vaccination

As an alternative to classic administration of a peptide-based vaccine, the technology of nucleic acid vaccination (also known as "nucleic acid immunisation", "genetic immunisation", and "gene immunisation") offers a number of attractive features.

First, in contrast to the traditional vaccine approach, nucleic acid vaccination does not require resource consuming large-scale production of the immunogenic agent (e.g. in the form of industrial scale fermentation of microorganisms producing modified amyloidogenic polypeptides). Furthermore, there is no need to device purification and refolding schemes for the immunogen. And finally, since nucleic acid vaccination relies on the biochemical apparatus of the vaccinated individual in order to produce

the expression product of the nucleic acid introduced, the optimum post-translational processing of the expression product is expected to occur; this is especially important in the case of autovaccination, since, as mentioned above, a significant
5 fraction of the original B-cell epitopes should be preserved in the modified molecule, and since B-cell epitopes in principle can be constituted by parts of any (bio)molecule (e.g. carbohydrate, lipid, protein etc.). Therefore, native glycosylation and lipidation patterns of the immunogen may very well be of
10 importance for the overall immunogenicity and this is best ensured by having the host producing the immunogen.

Hence, a preferred embodiment of the invention comprises effecting presentation of modified amyloidogenic polypeptide to the immune system by introducing nucleic acid(s) encoding the
15 modified amyloidogenic polypeptide into the animal's cells and thereby obtaining *in vivo* expression by the cells of the nucleic acid(s) introduced.

In this embodiment, the introduced nucleic acid is preferably DNA which can be in the form of naked DNA, DNA formulated with
20 charged or uncharged lipids, DNA formulated in liposomes, DNA included in a viral vector, DNA formulated with a transfection-facilitating protein or polypeptide, DNA formulated with a targeting protein or polypeptide, DNA formulated with Calcium precipitating agents, DNA coupled to an inert carrier molecule,
25 DNA encapsulated in a polymer, e.g. in PLGA (cf. the microencapsulation technology described in WO 98/31398) or in chitin or chitosan, and DNA formulated with an adjuvant. In this context it is noted that practically all considerations pertaining to the use of adjuvants in traditional vaccine formulation
30 apply for the formulation of DNA vaccines. Hence, all disclosures herein which relate to use of adjuvants in the context of polypeptide based vaccines apply *mutatis mutandis* to their use in nucleic acid vaccination technology.

As for routes of administration and administration schemes of polypeptide based vaccines which have been detailed above, these are also applicable for the nucleic acid vaccines of the invention and all discussions above pertaining to routes of administration and administration schemes for polypeptides apply *mutatis mutandis* to nucleic acids. To this should be added that nucleic acid vaccines can suitably be administered intravenously and intraarterially. Furthermore, it is well-known in the art that nucleic acid vaccines can be administered by use of a so-called gene gun, and hence also this and equivalent modes of administration are regarded as part of the present invention. Finally, also the use of a VLN in the administration of nucleic acids has been reported to yield good results, and therefore this particular mode of administration is particularly preferred.

Furthermore, the nucleic acid(s) used as an immunization agent can contain regions encoding the 1st, 2nd and/or 3rd moieties, e.g. in the form of the immunomodulating substances described above such as the cytokines discussed as useful adjuvants. A preferred version of this embodiment encompasses having the coding region for the analogue and the coding region for the immunomodulator in different reading frames or at least under the control of different promoters. Thereby it is avoided that the analogue or epitope is produced as a fusion partner to the immunomodulator. Alternatively, two distinct nucleotide fragments can be used, but this is less preferred because of the advantage of ensured co-expression when having both coding regions included in the same molecule.

Accordingly, the invention also relates to a composition for inducing production of antibodies against an amyloidogenic polypeptide, the composition comprising

- a nucleic acid fragment or a vector of the invention (cf. the discussion of vectors below), and

- a pharmaceutically and immunologically acceptable vehicle and/or carrier and/or adjuvant as discussed above.

Under normal circumstances, the variant-encoding nucleic acid is introduced in the form of a vector wherein expression is under control of a viral promoter. For more detailed discussions of vectors according to the invention, cf. the discussion below. Also, detailed disclosures relating to the formulation and use of nucleic acid vaccines are available, cf. Donnelly JJ et al, 1997, Annu. Rev. Immunol. 15: 617-648 and Donnelly JJ et al., 1997, Life Sciences 60: 163-172. Both of these references are incorporated by reference herein.

Live vaccines

A third alternative for effecting presentation of modified amyloidogenic polypeptide to the immune system is the use of live vaccine technology. In live vaccination, presentation to the immune system is effected by administering, to the animal, a non-pathogenic microorganism which has been transformed with a nucleic acid fragment encoding a modified amyloidogenic polypeptide or with a vector incorporating such a nucleic acid fragment. The non-pathogenic microorganism can be any suitable attenuated bacterial strain (attenuated by means of passaging or by means of removal of pathogenic expression products by recombinant DNA technology), e.g. *Mycobacterium bovis* BCG., non-pathogenic *Streptococcus* spp., *E. coli*, *Salmonella* spp., *Vibrio cholerae*, *Shigella*, etc. Reviews dealing with preparation of state-of-the-art live vaccines can e.g. be found in Saliou P, 1995, Rev. Prat. 45: 1492-1496 and Walker PD, 1992, Vaccine 10: 977-990, both incorporated by reference herein. For details about the nucleic acid fragments and vectors used in such live vaccines, cf. the discussion below.

As an alternative to bacterial live vaccines, the nucleic acid fragment of the invention discussed below can be incorporated in

a non-virulent viral vaccine vector such as a vaccinia strain or any other suitable pox virus.

Normally, the non-pathogenic microorganism or virus is administered only once to the animal, but in certain cases it may be
5 necessary to administer the microorganism more than once in a lifetime in order to maintain protective immunity. It is even contemplated that immunization schemes as those detailed above for polypeptide vaccination will be useful when using live or virus vaccines.

10 Alternatively, live or virus vaccination is combined with previous or subsequent polypeptide and/or nucleic acid vaccination. For instance, it is possible to effect primary immunization with a live or virus vaccine followed by subsequent
15 booster immunizations using the polypeptide or nucleic acid approach.

The microorganism or virus can be transformed with nucleic acid(s) containing regions encoding the 1st, 2nd and/or 3rd moieties, e.g. in the form of the immunomodulating substances described above such as the cytokines discussed as useful
20 adjuvants. A preferred version of this embodiment encompasses having the coding region for the analogue and the coding region for the immunomodulator in different reading frames or at least under the control of different promoters. Thereby it is avoided that the analogue or epitopes are produced as fusion partners to
25 the immunomodulator. Alternatively, two distinct nucleotide fragments can be used as transforming agents. Of course, having the 1st and/or 2nd and/or 3rd moieties in the same reading frame can provide as an expression product, an analogue of the invention, and such an embodiment is especially preferred according
30 to the present invention.

Use of the method of the invention in disease treatment

As will be appreciated from the discussions above, the provision of the method of the invention allows for control of diseases characterized by amyloid deposits. In this context, AD is the
5 key target for the inventive method but also other diseases characterized by amyloid deposits are feasible targets. Hence, an important embodiment of the method of the invention for down-regulating amyloid activity comprises treating and/or preventing and/or ameliorating AD or other diseases characterized by
10 amyloid deposition, the method comprising down-regulating amyloid according to the method of the invention to such an extent that the amount of amyloid is significantly decreased.

It is especially preferred that the reduction in amyloid results in an inversion of the balance between amyloid formation and
15 amyloid degradation/removal, i.e. that the rate of amyloid degradation/removal is brought to exceed the rate of amyloid formation. By carefully controlling the number and immunological impact of immunizations of the individual in need thereof it will be possible to obtain a balance over time which results in
20 a net reduction of amyloid deposits without having excessive adverse effects.

Alternatively, if in an individual the method of the invention cannot remove or reduce existing amyloid deposits, the method of the invention can be used to obtain a clinically significant
25 reduction in the formation of new amyloid, thereby significantly prolonging the time where the disease condition is non-debilitating. It should be possible to monitor the rate of amyloid depositing by either measuring the serum concentration of amyloid (which is believed to be in equilibrium with the deposited material), or by using positron-emission tomography (PET)
30 scanning, cf. Small GW, et al., 1996, Ann N Y Acad Sci 802: 70-78.

Other diseases and conditions where the present means and methods may be used in treatment or amelioration in an analogous way have been mentioned above in the "Background of the invention" (systemic amyloidosis, maturity onset diabetes, Parkinson's disease, Huntington's disease, fronto-temporal dementia and the prion-related transmissible spongiform encephalopathies) or are listed below in the section headed "other amyloidic diseases and proteins associated therewith".

Peptides, polypeptides, and compositions of the invention

10 As will be apparent from the above, the present invention is based on the concept of immunising individuals against the amyloidogenic antigen in order to obtain a reduced amount of pathology-related amyloid deposits. The preferred way of obtaining such an immunization is to use modified versions of
15 amyloidogenic polypeptide, thereby providing molecules which have not previously been disclosed in the art.

It is believed that the modified molecules discussed herein are inventive in their own right, and therefore an important part of the invention pertains to an analogue which is derived from an
20 animal amyloidogenic polypeptide wherein is introduced a modification which has as a result that immunization of the animal with the analogue induces production of antibodies reacting specifically with the unmodified amyloidogenic polypeptide. Preferably, the nature of the modification conforms with the
25 types of modifications described above when discussing various embodiments of the method of the invention when using modified amyloidogenic polypeptide. Hence, any disclosure presented herein pertaining to modified amyloidogenic molecules are relevant for the purpose of describing the amyloidogenic ana-
30 logues of the invention, and any such disclosures apply *mutatis mutandis* to the description of these analogues.

It should be noted that preferred modified amyloidogenic molecules comprises modifications which results in a polypeptide having a sequence identity of at least 70% with an amyloidogenic protein or with a subsequence thereof of at least 10 amino acids in length. Higher sequence identities are preferred, e.g. at least 75% or even at least 80, 85, 90, or 95%. The sequence identity for proteins and nucleic acids can be calculated as $(N_{ref} - N_{dif}) \cdot 100 / N_{ref}$, wherein N_{dif} is the total number of non-identical residues in the two sequences when aligned and wherein N_{ref} is the number of residues in one of the sequences. Hence, the DNA sequence AGTCAGTC will have a sequence identity of 75% with the sequence AATCAATC ($N_{dif}=2$ and $N_{ref}=8$).

The invention also pertains to compositions useful in exercising the method of the invention. Hence, the invention also relates to an immunogenic composition comprising an immunogenically effective amount of an amyloidogenic polypeptide which is a self-protein in an animal, said amyloidogenic polypeptide being formulated together with an immunologically acceptable adjuvant so as to break the animal's autotolerance towards the amyloidogenic polypeptide, the composition further comprising a pharmaceutically and immunologically acceptable diluent and/or vehicle and/or carrier and/or excipient. In other words, this part of the invention pertains to the formulations of naturally occurring amyloidogenic polypeptides which have been described in connection with embodiments of the method of the invention.

The invention also relates to an immunogenic composition comprising an immunologically effective amount of an analogue defined above, said composition further comprising a pharmaceutically and immunologically acceptable diluent and/or vehicle and/or carrier and/or excipient and optionally an adjuvant. In other words, this part of the invention concerns formulations of modified amyloidogenic polypeptide, essentially as described above. The choice of adjuvants, carriers, and vehicles is accordingly in line with what has been discussed above when

referring to formulation of modified and unmodified amyloidogenic polypeptide for use in the inventive method for the down-regulation of amyloid.

The polypeptides are prepared according to methods well-known in the art. Longer polypeptides are normally prepared by means of recombinant gene technology including introduction of a nucleic acid sequence encoding the analogue into a suitable vector, transformation of a suitable host cell with the vector, expression by the host cell of the nucleic acid sequence, recovery of the expression product from the host cells or their culture supernatant, and subsequent purification and optional further modification, e.g. refolding or derivatization.

Shorter peptides are preferably prepared by means of the well-known techniques of solid- or liquid-phase peptide synthesis. However, recent advances in this technology has rendered possible the production of full-length polypeptides and proteins by these means, and therefore it is also within the scope of the present invention to prepare the long constructs by synthetic means.

20 Nucleic acid fragments and vectors of the invention

It will be appreciated from the above disclosure that modified amyloidogenic polypeptides can be prepared by means of recombinant gene technology but also by means of chemical synthesis or semisynthesis; the latter two options are especially relevant when the modification consists in coupling to protein carriers (such as KLH, diphtheria toxoid, tetanus toxoid, and BSA) and non-proteinaceous molecules such as carbohydrate polymers and of course also when the modification comprises addition of side chains or side groups to an amyloidogenic polypeptide-derived peptide chain.

For the purpose of recombinant gene technology, and of course also for the purpose of nucleic acid immunization, nucleic acid fragments encoding modified amyloidogenic polypeptide are important chemical products. Hence, an important part of the invention pertains to a nucleic acid fragment which encodes an analogue of an amyloidogenic polypeptide, *i.e.* an amyloidogenic polypeptide-derived polypeptide which either comprises the natural sequence to which has been added or inserted a fusion partner or, preferably an amyloidogenic polypeptide-derived polypeptide wherein has been introduced a foreign T-cell epitope by means of insertion and/or addition, preferably by means of substitution and/or deletion. The nucleic acid fragments of the invention are either DNA or RNA fragments.

The nucleic acid fragments of the invention will normally be inserted in suitable vectors to form cloning or expression vectors carrying the nucleic acid fragments of the invention; such novel vectors are also part of the invention. Details concerning the construction of these vectors of the invention will be discussed in context of transformed cells and microorganisms below. The vectors can, depending on purpose and type of application, be in the form of plasmids, phages, cosmids, minichromosomes, or virus, but also naked DNA which is only expressed transiently in certain cells is an important vector. Preferred cloning and expression vectors of the invention are capable of autonomous replication, thereby enabling high copy-numbers for the purposes of high-level expression or high-level replication for subsequent cloning.

The general outline of a vector of the invention comprises the following features in the 5'-3' direction and in operable linkage: a promoter for driving expression of the nucleic acid fragment of the invention, optionally a nucleic acid sequence encoding a leader peptide enabling secretion (to the extracellular phase or, where applicable, into the periplasma) of or integration into the membrane of the polypeptide fragment, the

nucleic acid fragment of the invention, and optionally a nucleic acid sequence encoding a terminator. When operating with expression vectors in producer strains or cell-lines it is for the purposes of genetic stability of the transformed cell preferred
5 that the vector when introduced into a host cell is integrated in the host cell genome. In contrast, when working with vectors to be used for effecting *in vivo* expression in an animal (*i.e.* when using the vector in DNA vaccination) it is for security reasons preferred that the vector is incapable of being inte-
10 grated in the host cell genome; typically, naked DNA or non-integrating viral vectors are used, the choices of which are well-known to the person skilled in the art

The vectors of the invention are used to transform host cells to produce the modified amyloidogenic polypeptide of the invention.
15 Such transformed cells, which are also part of the invention, can be cultured cells or cell lines used for propagation of the nucleic acid fragments and vectors of the invention, or used for recombinant production of the modified amyloidogenic polypeptides of the invention. Alternatively, the transformed cells can
20 be suitable live vaccine strains wherein the nucleic acid fragment (one single or multiple copies) have been inserted so as to effect secretion or integration into the bacterial membrane or cell-wall of the modified amyloidogenic polypeptide.

Preferred transformed cells of the invention are microorganisms
25 such as bacteria (such as the species *Escherichia* [e.g. *E.coli*], *Bacillus* [e.g. *Bacillus subtilis*], *Salmonella*, or *Mycobacterium* [preferably non-pathogenic, e.g. *M. bovis* BCG]), yeasts (such as *Saccharomyces cerevisiae*), and protozoans. Alternatively, the transformed cells are derived from a multicellular organism such
30 as a fungus, an insect cell, a plant cell, or a mammalian cell. Most preferred are cells derived from a human being, cf. the discussion of cell lines and vectors below. Recent results have shown great promise in the use of a commercially available *Drosophila melanogaster* cell line (the Schneider 2 (S₂) cell line

and vector system available from Invitrogen) for the recombinant production of polypeptides in applicants' lab, and therefore this expression system is particularly preferred.

For the purposes of cloning and/or optimized expression it is preferred that the transformed cell is capable of replicating the nucleic acid fragment of the invention. Cells expressing the nucleic fragment are preferred useful embodiments of the invention; they can be used for small-scale or large-scale preparation of the modified amyloidogenic polypeptide or, in the case of non-pathogenic bacteria, as vaccine constituents in a live vaccine.

When producing the modified molecules of the invention by means of transformed cells, it is convenient, although far from essential, that the expression product is either exported out into the culture medium or carried on the surface of the transformed cell.

When an effective producer cell has been identified it is preferred, on the basis thereof, to establish a stable cell line which carries the vector of the invention and which expresses the nucleic acid fragment encoding the modified amyloidogenic polypeptide. Preferably, this stable cell line secretes or carries the analogue of the invention, thereby facilitating purification thereof.

In general, plasmid vectors containing replicon and control sequences which are derived from species compatible with the host cell are used in connection with the hosts. The vector ordinarily carries a replication site, as well as marking sequences which are capable of providing phenotypic selection in transformed cells. For example, *E. coli* is typically transformed using pBR322, a plasmid derived from an *E. coli* species (see, e.g., Bolivar et al., 1977). The pBR322 plasmid contains genes for ampicillin and tetracycline resistance and thus provides

easy means for identifying transformed cells. The pBR plasmid, or other microbial plasmid or phage must also contain, or be modified to contain, promoters which can be used by the prokaryotic microorganism for expression.

- 5 Those promoters most commonly used in recombinant DNA construction include the B-lactamase (penicillinase) and lactose promoter systems (Chang et al., 1978; Itakura et al., 1977; Goeddel et al., 1979) and a tryptophan (trp) promoter system (Goeddel et al., 1979; EP-A-0 036 776). While these are the most commonly
 10 used, other microbial promoters have been discovered and utilized, and details concerning their nucleotide sequences have been published, enabling a skilled worker to ligate them functionally with plasmid vectors (Siebwenlist et al., 1980). Certain genes from prokaryotes may be expressed efficiently in *E.*
 15 *coli* from their own promoter sequences, precluding the need for addition of another promoter by artificial means.

In addition to prokaryotes, eukaryotic microbes, such as yeast cultures may also be used, and here the promoter should be capable of driving expression. *Saccharomyces cerevisiae*, or
 20 common baker's yeast is the most commonly used among eukaryotic microorganisms, although a number of other strains are commonly available. For expression in *Saccharomyces*, the plasmid YRp7, for example, is commonly used (Stinchcomb et al., 1979; Kingsman et al., 1979; Tschemper et al., 1980). This plasmid already
 25 contains the *trp1* gene which provides a selection marker for a mutant strain of yeast lacking the ability to grow in tryptophan for example ATCC No. 44076 or PEP4-1 (Jones, 1977). The presence of the *trp1* lesion as a characteristic of the yeast host cell genome then provides an effective environment for detecting
 30 transformation by growth in the absence of tryptophan.

Suitable promoting sequences in yeast vectors include the promoters for 3-phosphoglycerate kinase (Hitzman et al., 1980) or other glycolytic enzymes (Hess et al., 1968; Holland et al.,

1978), such as enolase, glyceraldehyde-3-phosphate dehydrogenase, hexokinase, pyruvate decarboxylase, phosphofructokinase, glucose-6-phosphate isomerase, 3-phosphoglycerate mutase, pyruvate kinase, triosephosphate isomerase, phosphoglucose isomerase, and glucokinase. In constructing suitable expression plasmids, the termination sequences associated with these genes are also ligated into the expression vector 3' of the sequence desired to be expressed to provide polyadenylation of the mRNA and termination.

- 10 Other promoters, which have the additional advantage of transcription controlled by growth conditions are the promoter region for alcohol dehydrogenase 2, isocytochrome C, acid phosphatase, degradative enzymes associated with nitrogen metabolism, and the aforementioned glyceraldehyde-3-phosphate
- 15 dehydrogenase, and enzymes responsible for maltose and galactose utilization. Any plasmid vector containing a yeast-compatible promoter, origin of replication and termination sequences is suitable.

In addition to microorganisms, cultures of cells derived from

20 multicellular organisms may also be used as hosts. In principle, any such cell culture is workable, whether from vertebrate or invertebrate culture. However, interest has been greatest in vertebrate cells, and propagation of vertebrate in culture (tissue culture) has become a routine procedure in recent years

25 (Tissue Culture, 1973). Examples of such useful host cell lines are VERO and HeLa cells, Chinese hamster ovary (CHO) cell lines, and W138, BHK, COS-7 293, *Spodoptera frugiperda* (SF) cells (commercially available as complete expression systems from i.a. Protein Sciences, 1000 Research Parkway, Meriden, CT 06450,

30 U.S.A. and from Invitrogen), and MDCK cell lines. In the present invention, an especially preferred cell line is S₂ available from Invitrogen, PO Box 2312, 9704 CH Groningen, The Netherlands.

Expression vectors for such cells ordinarily include (if necessary) an origin of replication, a promoter located in front of the gene to be expressed, along with any necessary ribosome binding sites, RNA splice sites, polyadenylation site, and
5 transcriptional terminator sequences.

For use in mammalian cells, the control functions on the expression vectors are often provided by viral material. For example, commonly used promoters are derived from polyoma, Adenovirus 2, and most frequently Simian Virus 40 (SV40). The early and late
10 promoters of SV40 virus are particularly useful because both are obtained easily from the virus as a fragment which also contains the SV40 viral origin of replication (Fiers et al., 1978).
Smaller or larger SV40 fragments may also be used, provided there is included the approximately 250 bp sequence extending
15 from the *HindIII* site toward the *BglII* site located in the viral origin of replication. Further, it is also possible, and often desirable, to utilize promoter or control sequences normally associated with the desired gene sequence, provided such control sequences are compatible with the host cell systems.

20 An origin of replication may be provided either by construction of the vector to include an exogenous origin, such as may be derived from SV40 or other viral (e.g., Polyoma, Adeno, VSV, BPV) or may be provided by the host cell chromosomal replication mechanism. If the vector is integrated into the host cell chromosome,
25 the latter is often sufficient.

Identification of useful analogues

It will be clear to the skilled person that not all possible variants or modifications of naturally occurring amyloidogenic polypeptides will have the ability to elicit antibodies in an
30 animal which are cross-reactive with the natural form. It is, however, not difficult to set up an effective standard screen for modified amyloidogenic molecules which fulfill the minimum

requirements for immunological reactivity discussed herein. Hence, another part of the invention concerns a method for the identification of a modified amyloidogenic polypeptide which is capable of inducing antibodies against unmodified amyloidogenic polypeptide in an animal species where the unmodified amyloidogenic polypeptide is a (non-immunogenic) self-protein, the method comprising

- preparing, by means of peptide synthesis or genetic engineering techniques, a set of mutually distinct modified amyloidogenic polypeptides wherein amino acids have been added to, inserted in, deleted from, or substituted into the amino acid sequence of an amyloidogenic polypeptide of the animal species thereby giving rise to amino acid sequences in the set which comprise T-cell epitopes which are foreign to the animal species, or preparing a set of nucleic acid fragments encoding the set of mutually distinct modified amyloidogenic polypeptides,
- testing members of the set of modified amyloidogenic polypeptides or nucleic acid fragments for their ability to induce production of antibodies by the animal species against the unmodified amyloidogenic polypeptide, and
- identifying and optionally isolating the member(s) of the set of modified amyloidogenic polypeptides which significantly induces antibody production against unmodified amyloidogenic polypeptide in the species or identifying and optionally isolating the polypeptide expression products encoded by members of the set of nucleic acid fragments which significantly induces antibody production against unmodified amyloidogenic polypeptide in the animal species.

In this context, the "set of mutually distinct modified amyloidogenic polypeptides" is a collection of non-identical modified amyloidogenic polypeptides which have e.g. been selected on the basis of the criteria discussed above (e.g. in combination with studies of circular dichroism, NMR spectra,

and/or X-ray diffraction patterns). The set may consist of only a few members but it is contemplated that the set may contain several hundred members.

5 The test of members of the set can ultimately be performed *in vivo*, but a number of *in vitro* tests can be applied which narrow down the number of modified molecules which will serve the purpose of the invention.

Since the goal of introducing the foreign T-cell epitopes is to support the B-cell response by T-cell help, a prerequisite is
10 that T-cell proliferation is induced by the modified amyloidogenic polypeptide. T-cell proliferation can be tested by standardized proliferation assays *in vitro*. In short, a sample enriched for T-cells is obtained from a subject and subsequently kept in culture. The cultured T-cells are contacted with APCs of
15 the subject which have previously taken up the modified molecule and processed it to present its T-cell epitopes. The proliferation of T-cells is monitored and compared to a suitable control (e.g. T-cells in culture contacted with APCs which have processed intact, native amyloidogenic polypeptide). Alterna-
20 tively, proliferation can be measured by determining the concentration of relevant cytokines released by the T-cells in response to their recognition of foreign T-cells.

Having rendered highly probable that at least one modified amyloidogenic polypeptide of either type of set is capable of
25 inducing antibody production against amyloidogenic polypeptide, it is possible to prepare an immunogenic composition comprising at least one modified amyloid polypeptide which is capable of inducing antibodies against unmodified amyloidogenic polypeptide in an animal species where the unmodified amyloidogenic polypep-
30 tide is a self-protein, the method comprising admixing the member(s) of the set which significantly induces production of antibodies in the animal species which are reactive with the amyloidogenic polypeptide with a pharmaceutically and immunolo-

gically acceptable carrier and/or vehicle and/or diluent and/or excipient, optionally in combination with at least one pharmaceutically and immunologically acceptable adjuvant.

The above aspects of the invention pertaining to test of
5 polypeptide sets are conveniently carried out by initially preparing a number of mutually distinct nucleic acid sequences or vectors of the invention, inserting these into appropriate expression vectors, transforming suitable host cells (or host animals) with the vectors, and effecting expression of the
10 nucleic acid sequences of the invention. These steps can be followed by isolation of the expression products. It is preferred that the nucleic acid sequences and/or vectors are prepared by methods comprising exercise of a molecular amplification technique such as PCR or by means of nucleic acid synthesis.
15 sis.

Specific amyloidogenic targets

In addition to the proteins most often associated with Alzheimer's, APP, ApoE4 and Tau, there is long list of other proteins that have somehow been linked to AD, either by their direct
20 presence in plaques or tangles of AD brains or by their apparent genetic association with increased risk of developing AD. Most, if not all, of these antigens are together with the above-discussed A β , APP, presenilin and ApoE4, putative target proteins in the present invention.

25 **Alpha1-antichymotrypsin (ACT)** is a major component of SPs and is suggested to play an important role in the pathogenesis of the lesions in AD and cerebrovascular amyloidosis (CA) (Acta neuropathol, 1998, 96: 628-36). It interacts with A β *in vitro* and stimulates both formation and disruption of A β -42 fibrils
30 (JBC, 1998, 273: 28360-4).

Alpha2-macroglobulin was found by immunostaining in plaque cores in AD brains. A transmembrane fragment from the beta-subunit was found in plaque cores, while the soluble alpha fragment was found extracellularly in plaques. *Acta neuropathol*, 1998, 96: 628-36 and *Brain Res.*, 1997, 777: 223-227.

ABAD (A β -peptide binding alcohol dehydrogenase) binds with A β inside the cell. It is a neuronal enzyme present in normal cells but overexpressed in neurons affected by AD. A β is more toxic to cells that overexpress ABAD. ABAD is linked to the X-chromosome. Yan, 1997, *Nature* 389.

APLP1 and -2 (amyloid precursor like protein 1 and -2): Both proteins belong to the APP homologue super-family proteins, but lack the A β peptide region. Nevertheless, there is a significant staining of APLP in neuritic plaques. *Acta Neuropathol*, 1997, 94: 519-524.

AMY117 is a newly discovered protein in plaque-like lesions in the brains of people with AD which seems abundant, widespread, and "highly specific" for the disease. It is suspected that the protein, AMY117, may play a crucial role in the development and progression AD by forming these plaques. Interestingly, AMY117 containing plaques do not co-localise with those containing A β , thus defining a new characteristic manifestation of AD in addition to the well known A β containing plaques and Tau containing tangles. AMY117-positive plaques were found to be abundant in the brains of sporadic cases of AD and in brains from people with Down's syndrome, but "rare or absent" in brains of controls and of other neurodegenerative diseases (*Am J Pathol* 1997; 151: 69,80).

Bax: Monoclonal antibodies has detected Bax as a component of senile plaques in AD brains. Is also overexpressed in dystrophic neurites. *Acta Neuropathol*. 1998, 95: 407-412.

Bcl-2 has an unclear role. Overexpressed in glial cells surrounding plaques. *Acta Neuropathol.* 1998, 95: 407-412.

Bleomycin hydrolase is perhaps a beta-secretase. Anti bleomycin hydrolase immunoreactivity has been found in SP in AD (Brain Res. 1999, 830: 200-202). A certain bleomycin hydrolase genotype has been associated with increased risk of developing AD in some cases, while in others no correlation has been found (*Ann Neurol*, 1998, 44: 808-811 and *Ann Neurol*, 1999, 46: 136-137).

- 10 BRI/ABRI: ABRI is a 4 kD fragment of a putative transmembrane protein, encoded by the BRI gene on chromosome 13, found in amyloid plaques of people with familial British dementia (FBD). These patients have a mutation in the stop codon of the BRI gene that creates a longer open reading frame. Release of the 34
15 carboxy terminal amino acids of the altered protein generates the ABRI amyloid subunit. Antibodies against ABRI recognise both parenchymal and vascular lesions in the brain of FBD patients. The ABri peptide is deposited as amyloid fibrils and the resulting plaques are thought to lead to the neuronal dysfunction and
20 dementia that characterizes FBD (Vidal, R et. al., 1999, *Nature* 399).

Chromogranin A has been detected in some diffuse amyloid deposits and in dystrophic neurites surrounding these (*Brain Res*, 1991, 539: 143-50).

- 25 Clusterin/apoJ: This is a gene frequently isolated by differential screening in laboratories from different areas of molecular biology, since it is overexpressed in numerous cases of degenerative diseases such as AD and scrapie (*Biochem J* 1997 Nov 15;328(1):45-50 Michel D, Chatelain G, North S, Brun G).
- 30 CRF (corticotropin releasing factor) binding protein binds the 41 aa CRF peptide that is an important regulatory factor in stress responses in the brain. As most CRF is bound by CRF

binding protein, removing CRF binding protein (by immunotherapy) could lead to increased level of free CRF, which is believed to have a positive effect against AD. Behan, 1997, J. Neurochemistry, 68: 2053-2060.

- 5 **EDTF (endothelial-derived toxic factor):** A protein produced by microvessels from AD patients. Is specifically toxic to neuronal cells. WO 99/24468.

Heparan sulfate proteoglycans have been shown to co-localise with A β in SP's. Rat studies indicate that heparan sulfate
10 glycosaminoglycan is required for amyloid fibre formation (Neuron, 1994, 12: 219-234 and Acta neuropathol, 1998, 96: 628-36).

Human collapsin response mediator protein-2 is 65 kDa protein recognised in neurofibrillary tangles by a monoclonal antibody.
15 Incorporation into tangles may deplete soluble protein and lead to abnormal neuritic outgrowth, thus accelerating neuronal degeneration. JBC, 1998, 273: 9761-8.

Huntingtin (Huntington's disease protein): In HD, the Hunting-
20 tin protein is N-terminally expanded with polyglutamine. This form of Huntingtin is also found in NFT's in AD brains and in Pick's disease (Exp. Neurol, 1998, 150: 213-222).

ICAM-I is accumulated in SP's. Acta neuropathol, 1998, 96: 628-36 and Am. J Pathol. 1994, 144: 104-16.

25 **IL-6** is associated with neurofibrillar changes and is found in the centre of plaques. Has been proposed to be a triggering event in AD. Is strongly amplified in astrocytes by the active peptide 25-35 of A β . Brain Res., 1997, 777: 223-227 and Behav Brain Res, 1996, 78: 37-41.

30 **Lysosome-associated antigen CD68** is recognised by antibody KP-1 in NFT's and SP's. Thus, lysosomes may play a role in the

formation of tangles and plaques. Dement Geriatr Cogn Disord, 1998, 9: 13-19.

P21 ras is involved as a primary step in the elevation of growth factors and mitogens seen at early stages of AD development.

5 Neuroscience, 1999, 91: 1-5.

PLC-delta 1 (phospholipase C isoenzyme delta 1) is abnormally accumulated in NFT's and neurites surrounding plaque cores. Is intracellular. Alzheimer Dis Assoc Disord, 1995, 9: 15-22.

Serum amyloid P component (SAP) is a normal plasma constituent
10 that is present in all types of amyloid deposits, including that of AD (JBC, 1995, 270: 26041-4). It is observed in both SP's and NFT's. In some studies it was shown to promote A β aggregation and to prevent proteolysis of fibrils (Biochem Biophys Res commun, 1995, 211: 349v - 53 and PNAS, 1995, 92: 4299-4303)
15 while another study indicates that SAP inhibit A β fibril formation (JBC, 1995, 270: 26041 - 4).

Synaptophysin has been detected in some diffuse amyloid deposits and in dystrophic neurites surrounding these. (Brain Res, 1991, 539: 143-50).

20 **Synuclein (alpha-synuclein or NACP):** The non-A beta component of AD amyloid (NAC) was identified biochemically as the second major component in the amyloid purified from brain tissue of AD patients. NAC, derived from its 140 amino acid long precursor, NACP, is at least 35 amino acids long (NAC35) although its amino
25 terminus is not definitely determined. An NAC monoclonal antibody immunostains SP's in AD brains, but does not react with NACP (Biochemistry 34 (32): 10139-10145 (Aug 15 1995) Iwai A, Yoshimoto M, Masliah E, Saitoh T). NAC self-oligomers in the presence of A β . New evidence points to a potential role for this
30 molecule in synaptic damage and neurotoxicity via amyloid-like

fibril formation and mitochondrial dysfunction. Brain Pathol 1999 Oct;9(4):707-20. FEBS Lett, 1998, 421:73-76. A part of NACP has high homology to the C-terminal amyloid fragment of APP and to a region of scrapie prion protein (PrPSc). Synuclein is a
 5 major causative factor of Parkinson's (Chem Biol, 1995, 2: 163-9).

TGF-b1 (transforming growth factor b1): Overexpression of TGF-b1 with mutant APP in TG mice accelerates deposition of A β . Thus, TGF-b1 is believed to be involved in initiating or promoting
 10 amyloid plaque formation (Wyss-Coray, 1997, Nature 389).

Other amyloidic diseases and proteins associated therewith

In addition to the above mentioned proteins that are potentially involved in AD and AD like diseases (Huntington's, Parkinson's, FBD and other forms of dementia), there are a relatively large
 15 number of diseases other than AD where amyloid formation is involved in triggering the disease or in causing the symptoms of the disease. Although the proteins involved in these diseases vary in nature they share the same features which define amyloid, cf. above. The following table lists a number of these
 20 amyloidic disorders and the proteins causing them.

Diversity of amyloid fibril proteins

	Clinical Syndrome	Fibril subunit	Precursor structure
	Monoclonal protein systemic (AL) amyloidosis	Full length or fragments of V domain of IG light chain	All β
25	Reactive systemic (AA) amyloidosis	76-residue N-terminal fragment of amyloid A protein	α/β
	Familial amyloidotic polyneuropathy	Full-length or fragments of transthyretin variants	All β
	Hereditary ApoA1 amyloidosis	N-terminal fragments (~90 residues) of ApoA1 variants	(α/β)
30	Hereditary lysozyme amyloidosis	Full-length lysozyme variants	$\alpha + \beta$
	Type II diabetes mellitus	37-residue fragment of islet-amyloid polypeptide	Unknown
	Insulin-related amyloid	Full-length wild-type insulin	$\alpha + \beta$
	Transmissible spongiform	Full-length or fragments of	$\alpha + \beta$

	Clinical Syndrome	Fibril subunit	Precursor structure
	encephalopathis	prion protein	
	Medullary carcinoma of the thyroid	Fragments of calcitonin	Unknown
	Senile systemic amyloidosis	Full-length or fragments of transthyretin	All β
5	Hemodialysis-related amyloidosis	Full-length, wild-type b-2 microglobulin	All β
	Isolated atrial amyloidosis	Atrial natriuretic factor	Unknown
	Hereditary cerebral amyloid angiopathy	110-residue fragment of variant cystatin	$\alpha + \beta$
10	Finnish hereditary amyloidosis	71-residue fragment of gelsolin variants	α/β
	Hereditary fibrinogen a-chain amyloidosis	Fragments of fibrinogen a-chain variants	Unknown

These proteins are, like the proteins involved in AD, all potential targets for the immunization strategy suggested
 15 herein.

It is contemplated that most methods for immunizing against amyloidogenic polypeptides should be restricted to immunization giving rise to antibodies cross-reactive with the native amyloidogenic polypeptide. Nevertheless, in some cases it will
 20 be of interest to induce cellular immunity in the form of CTL responses against cells which present MHC Class I epitopes from the amyloidogenic polypeptides - this can be expedient in those cases wherein reduction in the number of cells producing the amyloidogenic polypeptides does not constitute a serious adverse
 25 effect. In such cases where CTL responses are desired it is preferred to utilise the teachings of Applicant's PCT/DK99/00525 (corresponding to USSN 09/413,186). The disclosures of these two documents are hereby incorporated by reference herein.

In the following non-limiting example, focus has been put on the
 30 development of a A β based autovaccine against AD. However, the principles set forth herein apply equally to any amyloid protein.

EXAMPLE

The Auto Vaccination approach for Immunizing against AD

The fact that A β protein knock out mice does not show any abnormalities or adverse side effects, suggest that removal or
5 lowering the amounts of A β will be safe, Zheng H. (1996).

Published experiments where transgenic animals are immunized against the transgenic human A β protein suggest that if it was possible to break the self tolerance, down-regulation of A β could be obtained by auto-reactive antibodies. These experiments
10 further suggest that such down regulation of A β potentially would both prevent the formation of plaques, and even clear already formed A β plaques from the brain, cf. Schenk et al. (1999). But, traditionally it is not possible to raise antibodies against self-proteins.

15 The published data does thus not provide the means for breaking true self-tolerance towards true self-proteins. Nor does the data provide information on how to ensure that the immune reaction is directed solely or predominantly towards the A β deposits, and not towards the cell membrane bound A β precursor
20 protein (APP), if this is deemed necessary. An immune response generated using the existing technology would presumably generate an immune response towards self-proteins in a unregulated way so unwanted and excessive auto-reactivity towards parts the A β protein may be generated. Hence, using existing immunization
25 strategies will most likely be unable to generate strong immune responses towards self-proteins and will furthermore be unsafe due to potential strong cross-reactivity towards membrane bound APP which is present on a large number of cells in the CNS.

The present invention provides the means of effectively generating a strong regulated immune response towards true self-
30 proteins which potentially could form plaques and cause serious

disease in the CNS or in other compartments of the body. A safe and efficacious human A β protein therapeutic vaccine will be developed by using this technology for the treatment of AD.

In light of this, it is possible to anticipate that AD, a disease predicted to cripple the health care system in the next century, could be cured, or such vaccines described could at least constitute an effective therapeutical approach for treatment of the symptoms and progression of this disease. This technique represents a entirely new immunological approach to blocking amyloid deposition in AD and other neurologic diseases as well.

In the following table, 35 contemplated constructs are indicated. All positions given in the table are relative to the starting Methionine of APP (first amino acid in SEQ ID NO: 2) and include both the starting and ending amino acid, e.g. the 672 - 714 fragment includes both amino acid 672 and 714. The starting and ending positions for P2 and P30 indicate that the epitope substitutes a part of the APP fragment at the positions indicated (both positions included in the substitution) - in most constructs, the introduced epitopes substitutes a fragment of the length of the epitope. The asterisks in the table have the following meaning:

- *) Only one position for P2 and P30 indicates that the epitope has been inserted into the APP derivative at the position indicated (the epitope begins at the amino acid C-terminally adjacent to the given position).
- **) Construction 34 contains three identical APP fragments separated by P30 and P2, respectively.
- 30 ***) Construction 35 contains nine identical APP fragments separated by alternating P30 and P2 epitopes.

APP Autovac constructions

Var. No.	Start of APP segment relative to aa 1 of APP	End of APP segment relative to aa 1 of APP	Position of P2 epitope relative to aa 1 of APP	Position of P30 epitope relative to aa 1 of APP	Molecule length
1	630	770	656 - 670	635 - 655	141
2	630	714	656 - 670	635 - 655	85

35	672	714	34 X 3***	34 X 3***	165

The part of APP against which it most interesting to generate a response is the 43 amino acid A β core peptide (A β -43, corresponding to SEQ ID NO: 2, residues 672-714) that is the main constituent of amyloid plaques in AD brains. This APP fragment
5 is part of all constructions listed above.

Variants 1 and 2 comprise a portion of APP upstream of A β -43 where the model epitopes P2 and P30 have been placed. Variants 1 and 3-8 all comprise the C-100 fragment which has been shown to be neurotoxic - the C-100 fragment corresponds to amino acid
10 residues 714-770 of SEQ ID NO: 2. In variants 3-5 the epitopes substitutes a part of the C-100 fragment while the in variants 6-8 have been inserted into C-100.

Variants 9-35 contain only the core A β -43 protein. In variants 9-13, P2 and P30 are fused to either end of A β -43; in 14-21 P2
15 and P30 substitutes part of A β -43; in 22-33 P2 and P30 are inserted into A β -43; 34 contains three identical A β -43 fragments spaced by P30 and P2, respectively; 35 contains 9 A β -43 repeats spaced by alternating P2 and P30 epitopes.

See Fig. 1 and the table above for details.

20 One further type of construct is especially preferred. Since one goal of the present invention is to avoid destruction of the cells producing APP whereas removal of A β is desired, it seems feasible to prepare autovaccine constructs comprising only parts of A β which are not exposed to the extracellular phase when
25 present in APP. Thus, such constructs would need to contain at least one B-cell epitope derived from the amino acid fragment defined by amino acids 700-714 in SEQ ID NO: 2. Since such a short polypeptide fragment is predicted to be only weakly immunogenic it is preferred that such an autovaccine construct
30 consists of several copies of the B-cell epitope, e.g. in the form of a construct having the structure shown in Formula I in

the detailed disclosure of the present invention, cf. above. In that version of Formula I, the terms amyloid_{a1}-amyloid_{ex} are x B-cell epitope containing amino acid sequences derived from amino acids 700-714 of SEQ ID NO: 2.

CLAIMS

1. A method for *in vivo* down-regulation of amyloid protein in an animal, including a human being, the method comprising effecting presentation to the animal's immune system of an immunogenically effective amount of
- at least one amyloidogenic polypeptide or subsequence thereof which has been formulated so that immunization of the animal with the amyloidogenic polypeptide or subsequence thereof induces production of antibodies against the amyloidogenic polypeptide, and/or
 - at least one analogue of the amyloidogenic polypeptide wherein is introduced at least one modification in the amino acid sequence of the amyloidogenic polypeptide which has as a result that immunization of the animal with the analogue induces production of antibodies against the amyloidogenic polypeptide.
2. The method according to claim 1, wherein is presented an analogue with at least one modification of the amino acid sequence of the amyloidogenic polypeptide.
3. The method according to claim 2, wherein the modification has as a result that a substantial fraction of B-cell epitopes of the amyloidogenic polypeptide are preserved and that
- at least one foreign T helper lymphocyte epitope (T_H epitope) is introduced, and/or
 - at least one first moiety is introduced which effects targeting of the modified molecule to an antigen presenting cell (APC) or a B-lymphocyte, and/or
 - at least one second moiety is introduced which stimulates the immune system, and/or
 - at least one third moiety is introduced which optimizes presentation of the modified amyloidogenic polypeptide to the immune system.

4. The method according to claim 3, wherein the modification includes introduction as side groups, by covalent or non-covalent binding to suitable chemical groups in the amyloidogenic polypeptide or a subsequence thereof, of the foreign T_H epitope
5 and/or of the first and/or of the second and/or of the third moiety.

5. The method according to claim 3 or 4, wherein the modification includes amino acid substitution and/or deletion and/or insertion and/or addition.

10 6. The method according to claim 5, wherein the modification results in the provision of a fusion polypeptide.

7. The method according to claim 5 or 6, wherein introduction of the amino acid substitution and/or deletion and/or insertion and/or addition results in a substantial preservation of the
15 overall tertiary structure of the amyloidogenic.

8. The method according to any one of claims 2-7, wherein the modification includes duplication of at least one B-cell epitope of the amyloidogenic polypeptide and/or introduction of a hapten.

20 9. The method according to any one of claims 3-8, wherein the foreign T-cell epitope is immunodominant in the animal.

10. The method according to any one of claims 3-9, wherein the foreign T-cell epitope is promiscuous.

11. The method according to claim 10, wherein the at least one
25 foreign T-cell epitope is selected from a natural promiscuous T-cell epitope and an artificial MHC-II binding peptide sequence.

12. The method according to claim 11, wherein the natural T-cell epitope is selected from a Tetanus toxoid epitope such as P2 or

P30, a diphtheria toxoid epitope, an influenza virus hemagglutinin epitope, and a *P. falciparum* CS epitope.

13. The method according to any one of claims 3-12, wherein the first moiety is a substantially specific binding partner for a B-lymphocyte specific surface antigen or for an APC specific surface antigen such as a hapten or a carbohydrate for which there is a receptor on the B-lymphocyte or the APC.

14. The method according to any one of claims 3-13, wherein the second moiety is selected from a cytokine, a hormone, and a heat-shock protein.

15. The method according to claim 6, wherein the cytokine is selected from, or is an effective part of, interferon γ (IFN- γ), Flt3L, interleukin 1 (IL-1), interleukin 2 (IL-2), interleukin 4 (IL-4), interleukin 6 (IL-6), interleukin 12 (IL-12), interleukin 13 (IL-13), interleukin 15 (IL-15), and granulocyte-macrophage colony stimulating factor (GM-CSF), and the heat-shock protein is selected from, or is an effective part of, HSP70, HSP90, HSC70, GRP94, and calreticulin (CRT).

16. The method according to any one of claims 3-15, wherein the third moiety is of lipid nature, such as a palmitoyl group, a myristyl group, a farnesyl group, a geranyl-geranyl group, a Π -anchor, and an N-acyl diglyceride group.

17. The method according to any one of the preceding claims, wherein the amyloidogenic polypeptide or subsequence thereof has been modified so as to preserve B-cell epitopes which are not exposed to the extracellular phase when present in a cell-bound form of the precursor polypeptide for the amyloidogenic polypeptide.

18. The method according to claim 17, wherein the amyloidogenic polypeptide has been modified so as to lack at least one B-cell

epitope which is exposed to the extracellular phase when present in a cell-bound form of the precursor polypeptide.

19. The method according to any of the preceding claims which comprises a substitution of at least one amino acid sequence
5 within the amyloidogenic polypeptide with an amino acid sequence of equal or different length which gives rise to a foreign T_H epitope in the analogue.

20. The method according to any of the preceding claims, wherein the amyloidogenic polypeptide is selected from the group consisting of beta-amyloid (A β), amyloid precursor protein (APP),
10 ApoE4, presenillin, a prion polypeptide, Alpha1-antichymotrypsin (ACT), Alpha2-macroglobulin, ABAD (A β -peptide binding alcohol dehydrogenase), APLP1 and -2 (amyloid precursor like protein 1 and -2), AMY117, Bax, Bcl-2, Bleomycin hydrolase, BRI/ABRI,
15 Chromogranin A, Clusterin/apoJ, CRF (corticotropin releasing factor) binding protein, EDTF (endothelial-derived toxic factor), a heparan sulfate proteoglycans, human collapsin response mediator protein-2, huntingtin, ICAM-I, IL-6, lysosome-associated antigen CD68, P21 ras, PLC-delta 1 (phospholipase C isoenzyme delta 1), Serum amyloid P component (SAP), Synaptophysin,
20 Synuclein (alpha-synuclein or NACP), TGF-b1 (transforming growth factor b1), full length or a fragment of V domain of IG light chain, a 76-residue N-terminal fragment of amyloid A protein, full-length or a fragment of transthyretin variants, an N-terminal fragment of ApoA1 variants, a full-length lysozyme
25 variant, a 37-residue fragment of islet-amyloid polypeptide, a full-length wild-type insulin, full-length or a fragment of prion protein, a fragment of calcitonin, full-length or a fragment of transthyretin, full-length wild-type β -2 microglobulin, atrial natriuretic factor, a 110-residue fragment of
30 variant cystatin, a 71-residue fragment of gelsolin variants, and a fragment of fibrinogen α -chain variants.

21. The method according to any of the preceding claims, wherein the amyloidogenic polypeptide is (A β).

22. The method according to claim 21, wherein the amino acid sequence containing the foreign T_H epitope is introduced into
5 the amyloidogenic polypeptide as schematically shown for the P2 and P30 epitopes in Fig. 1.

23. The method according to claim 22, wherein the amyloidogenic polypeptide comprises an amino acid sequence corresponding to amino acids 700-714 in SEQ ID NO: 2, such as amino acid residues
10 672-714 in SEQ ID NO: 2.

24. The method according to claim 23, wherein the amyloidogenic polypeptide comprises the amino acid sequence corresponding to amino acids 672-714 in SEQ ID NO: 2, wherein is inserted an amino acid sequence which gives rise to a foreign T_H epitope in
15 the analogue.

25. The method according to claim 23, wherein the amyloidogenic polypeptide comprises an amino acid sequence corresponding to amino acids 672-714 of SEQ ID NO: 2, wherein at least one amino acid sequence is substituted by an amino acid sequence of equal
20 or different length so as to give rise to a foreign T_H epitope.

26. The method according to any one of the preceding claims, wherein presentation to the immune system is effected by having at least two copies of the amyloidogenic polypeptide, the subsequence thereof or the modified amyloidogenic polypeptide
25 covalently or non-covalently linked to a carrier molecule capable of effecting presentation of multiple copies of antigenic determinants.

27. The method according to any the preceding claims, wherein the amyloidogenic polypeptide, the subsequence thereof, or the
30 modified amyloidogenic polypeptide has been formulated with an

adjuvant which facilitates breaking of autotolerance to autoantigens.

28. The method according to any one of the preceding claims, wherein an effective amount of the amyloidogenic polypeptide or
5 the analogue of the amyloidogenic polypeptide is administered to the animal via a route selected from the parenteral route such as the intradermal, the subdermal, the intracutaneous, the subcutaneous, and the intramuscular routes; the peritoneal route; the oral route; the buccal route; the sublingual route;
10 the epidural route; the spinal route; the anal route; and the intracranial route.

29. The method according to claim 28, wherein the effective amount is between 0.5 µg and 2,000 µg of the amyloidogenic polypeptide, the subsequence thereof or the analogue thereof.

15 30. The method according to claim 28 or 29, wherein the amyloidogenic polypeptide or analogue is contained in a virtual lymph node (VLN) device.

31. The method according to any one of claims 1-21, wherein presentation of modified amyloidogenic polypeptide to the immune
20 system is effected by introducing nucleic acid(s) encoding the modified amyloidogenic polypeptide into the animal's cells and thereby obtaining *in vivo* expression by the cells of the nucleic acid(s) introduced.

32. The method according to claim 31, wherein the nucleic acid-
25 (s) introduced is/are selected from naked DNA, DNA formulated with charged or uncharged lipids, DNA formulated in liposomes, DNA included in a viral vector, DNA formulated with a transfection-facilitating protein or polypeptide, DNA formulated with a targeting protein or polypeptide, DNA formulated with
30 Calcium precipitating agents, DNA coupled to an inert carrier

molecule, DNA encapsulated in chitin or chitosan, and DNA formulated with an adjuvant.

33. The method according to claim 32, wherein the nucleic acid(s) is/are contained in a VLN device.

5 34. The method according to any one of claims 22-33, which includes at least one administration/introduction per year, such as at least 2, at least 3, at least 4, at least 6, and at least 12 administrations/introductions.

-- 10 35. A method for treating and/or preventing and/or ameliorating Alzheimer's disease or other diseases and conditions characterized by amyloid deposits, the method comprising down-regulating amyloid according to the method of any one of claims 1-34 to such an extent that the total amount of amyloid is decreased or that the rate of amyloid formation is reduced with clinical
15 significance.

36. An analogue of an amyloidogenic polypeptide which is derived from an animal amyloidogenic polypeptide wherein is introduced a modification which has as a result that immunization of the animal with the analogue induces production of antibodies
20 against the amyloidogenic polypeptide.

37. An analogue according to claim 36, wherein the modification is as defined in any one of claims 1-19 and 22-25.

38. An immunogenic composition comprising
- an immunogenically effective amount of an amyloidogenic
25 polypeptide autologous in an animal, said amyloidogenic polypeptide being formulated together with an immunologically acceptable adjuvant so as to break the animal's autotolerance towards the amyloidogenic polypeptide, the composition further comprising a pharmaceutically and
30 immunologically acceptable carrier and/or vehicle, or

- an immunogenically effective amount of an analogue according to claim 36 or 37, the composition further comprising a pharmaceutically and immunologically acceptable carrier and/or vehicle and optionally an adjuvant.

5 39. A nucleic acid fragment which encodes an analogue according to claim 36 or 37.

40. A vector carrying the nucleic acid fragment according to claim 39.

41. The vector according to claim 40 which is capable of autonomous replication.

42. The vector according to claim 40 or 41 which is selected from the group consisting of a plasmid, a phage, a cosmid, a mini-chromosome, and a virus.

43. The vector according to any one of claims 40-42, comprising, in the 5'→3' direction and in operable linkage, a promoter for driving expression of the nucleic acid fragment according to claim 39, optionally a nucleic acid sequence encoding a leader peptide enabling secretion of or integration into the membrane of the polypeptide fragment, the nucleic acid fragment according to claim 39, and optionally a terminator.

44. The vector according to any one of claims 40-43 which, when introduced into a host cell, is capable or incapable of being integrated in the host cell genome.

45. The vector according to claim 43 or 44, wherein a promoter drives expression in a eukaryotic cell and/or in a prokaryotic cell.

46. A transformed cell carrying the vector of any one of claims 40-45.

47. The transformed cell according to claim 46 which is capable of replicating the nucleic acid fragment according to claim 39.

48. The transformed cell according to claim 47, which is a microorganism selected from a bacterium, a yeast, a protozoan, or a cell derived from a multicellular organism selected from a fungus, an insect cell such as an S₂ or an SF cell, a plant cell, and a mammalian cell.

49. The transformed cell according to any one of claims 46-48, which expresses the nucleic acid fragment according to claim 39.

50. The transformed cell according to claim 49, which secretes or carries on its surface, the analogue according to claim 36 or 37.

51. The method according to any one of claims 1-19 and 22-25, wherein presentation to the immune system is effected by administering a non-pathogenic microorganism or virus which is carrying a nucleic acid fragment which encodes and expresses the amyloidogenic polypeptide or analogue.

52. A composition for inducing production of antibodies against an amyloidogenic polypeptide, the composition comprising

- a nucleic acid fragment according to claim 39 or a vector according to any one of claims 40-45, and
- a pharmaceutically and immunologically acceptable carrier and/or vehicle and/or adjuvant.

53. A stable cell line which carries the vector according to any one of claims 40-45 and which expresses the nucleic acid fragment according to claim 39, and which optionally secretes or carries the analogue according to claim 36 or 37 on its surface.

54. A method for the preparation of the cell according to any one of claims 46-50, the method comprising transforming a host

cell with the nucleic acid fragment according to claim 39 or with the vector according to any one of claims 40-45.

55. A method for the identification of a modified amyloidogenic polypeptide which is capable of inducing antibodies against
5 unmodified amyloidogenic polypeptide in an animal species where the unmodified amyloidogenic polypeptide is a self-protein, the method comprising

- preparing, by means of peptide synthesis or genetic engineering techniques, a set of mutually distinct modified
10 amyloidogenic polypeptides wherein amino acids have been added to, inserted in, deleted from, or substituted into the amino acid sequence of an amyloidogenic polypeptide of the animal species thereby giving rise to amino acid sequences in the set which comprise T-cell epitopes which are
15 foreign to the animal species, or preparing a set of nucleic acid fragments encoding the set of mutually distinct modified amyloidogenic polypeptides,
- testing members of the set of modified amyloidogenic polypeptides or nucleic acid fragments for their ability to
20 induce production of antibodies by the animal species against the unmodified amyloidogenic polypeptide, and
- identifying and optionally isolating the member(s) of the set of modified amyloidogenic polypeptides which significantly induces antibody production against unmodified
25 amyloidogenic polypeptide in the species or identifying and optionally isolating the polypeptide expression products encoded by members of the set of nucleic acid fragments which significantly induces antibody production against unmodified amyloidogenic polypeptide in the animal species.

30 56. A method for the preparation of an immunogenic composition comprising at least one modified amyloidogenic polypeptide which is capable of inducing antibodies against unmodified amyloidogenic polypeptide in an animal species where the unmodified

amyloidogenic polypeptide is a self-protein, the method comprising

- preparing, by means of peptide synthesis or genetic engineering techniques, a set of mutually distinct modified amyloidogenic polypeptides wherein amino acids have been added to, inserted in, deleted from, or substituted into the amino acid sequence of an amyloidogenic polypeptide of the animal species thereby giving rise to amino acid sequences in the set comprising T-cell epitopes which are foreign to the animal,
- testing members of the set for their ability to induce production of antibodies by the animal species against the unmodified amyloidogenic polypeptide, and
- admixing the member(s) of the set which significantly induces production of antibodies in the animal species which are reactive with the amyloidogenic polypeptide with a pharmaceutically and immunologically acceptable carrier and/or vehicle, optionally in combination with at least one pharmaceutically and immunologically acceptable adjuvant.

57. The method according to claim 55 or 56, wherein preparation of the members of the set comprises preparing mutually distinct nucleic acid sequences, each sequence being a nucleic acid sequence according to claim 39, inserting the nucleic acid sequences into appropriate expression vectors, transforming suitable host cells or host animals with the vectors, and effecting expression of the nucleic acid sequences, optionally followed by isolating the expression products.

58. The method according to claim 57, wherein the preparation of the nucleic acid sequences and/or the vectors is achieved by the aid of a molecular amplification technique such as PCR or by the aid of nucleic acid synthesis.

59. Use of an amyloidogenic polypeptide or a subsequence thereof for the preparation of an immunogenic composition comprising an adjuvant for down-regulating amyloid in an animal.

60. Use of an amyloidogenic polypeptide or a subsequence thereof for the preparation of an immunogenic composition comprising an adjuvant for the treatment, prophylaxis or amelioration of Alzheimer's disease or other conditions characterized by amyloid deposits.

61. Use of an analogue of an amyloidogenic polypeptide for the preparation of an immunogenic composition optionally comprising an adjuvant for down-regulating amyloid in an animal.

62. Use of an analogue of an amyloidogenic polypeptide for the preparation of an immunogenic composition optionally comprising an adjuvant for the treatment, prophylaxis or amelioration of Alzheimer's disease or other conditions characterized by amyloid deposits.
